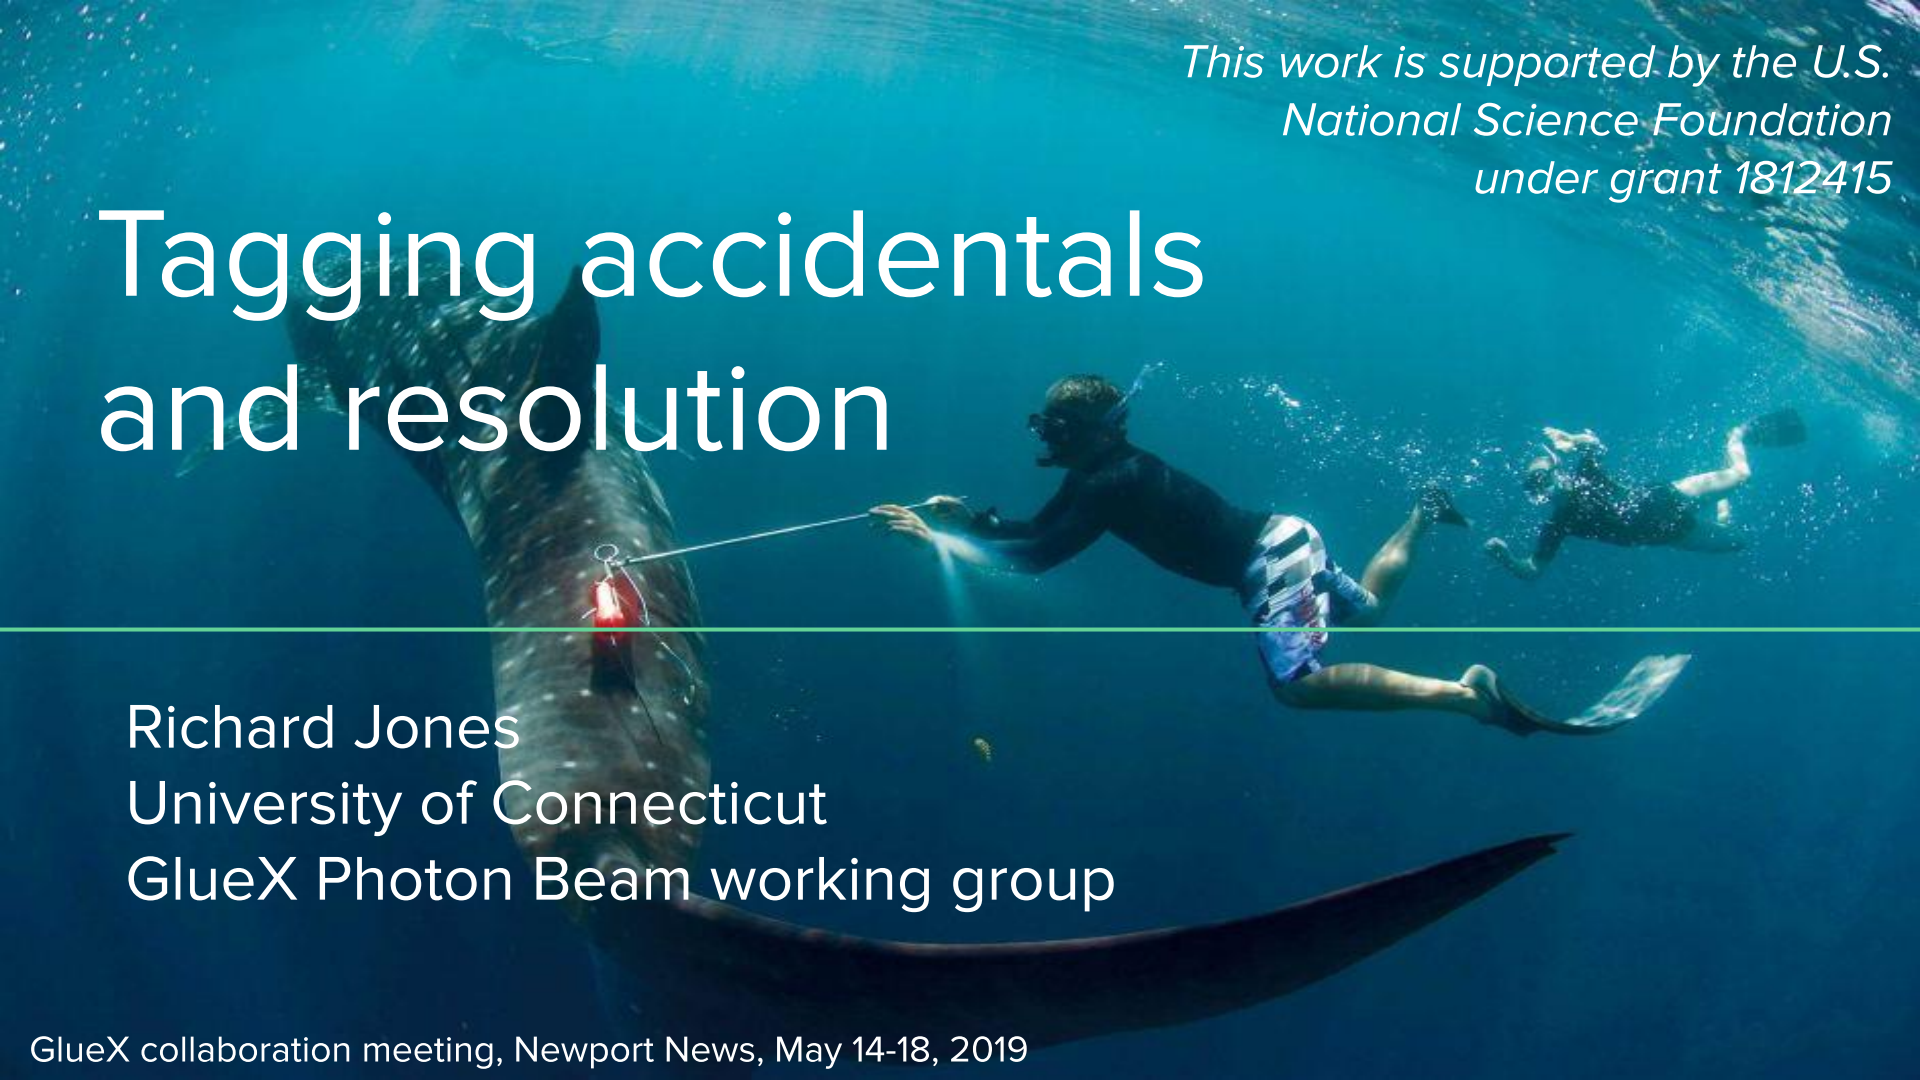
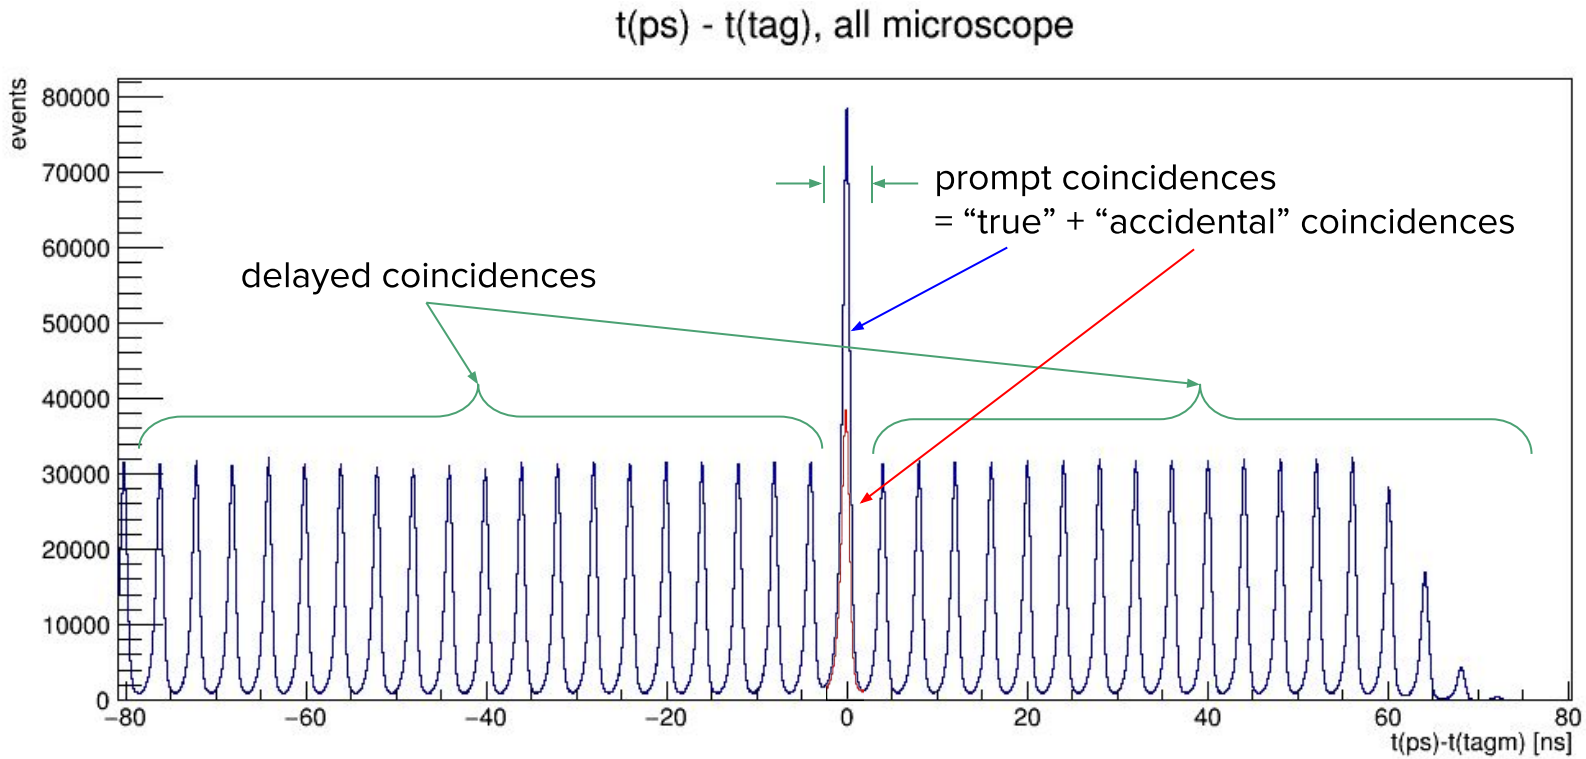
Tagging accidentals and resolution



Richard Jones
University of Connecticut
GlueX Photon Beam working group

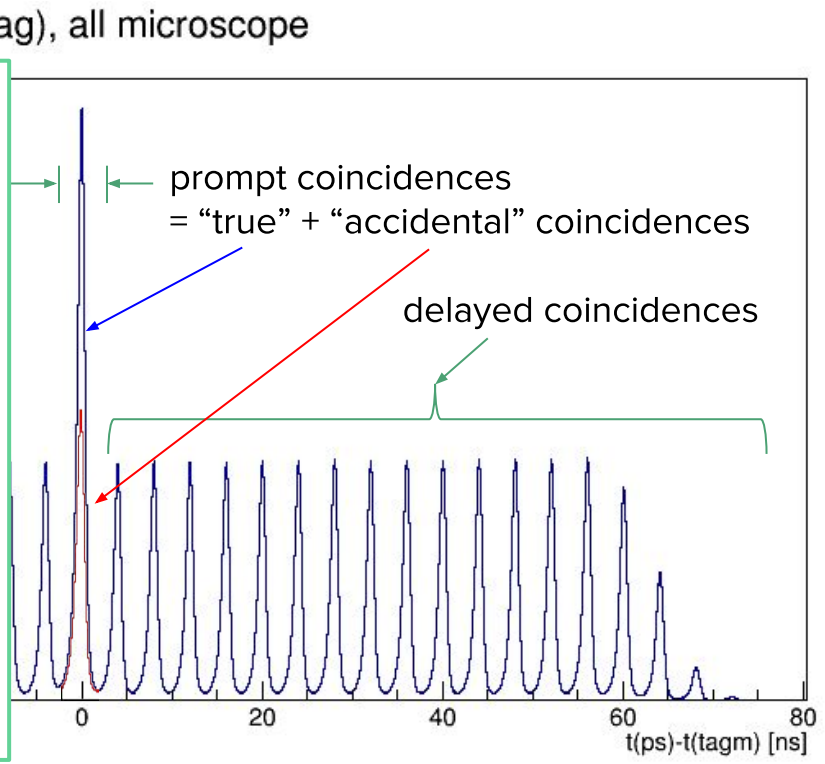
GlueX collaboration meeting, Newport News, May 14-18, 2019

Tagger accidentals: *definitions*



Tagger accidentals: *assumptions*

1. ***All events*** in the delayed peaks are identical <u>in character</u> to the ***accidentals*** in the prompt peak.
2. They need not be identical <u>in counts</u> -- *in general, they are not.*
3. Ratio of counts in delayed peaks to accidentals in the prompt peak is determined empirically.



Tagger accidentals: *derivation*

- *ignoring electronics dead time,*

$$T_i(E) = N_i\ p(E)$$

number of trues in beam pulse i, tagger energy E, for N_i tagged photons, trigger probability $p(E)$.

$$A_i(E) = N_i^2\ p(E)\,\epsilon(E)$$

number of accidentals in beam pulse i, for given tagger detection efficiency $\epsilon(E)$.

$$D_{ij}(E) = N_i N_j\ p(E)\,\epsilon(E)$$

number of delayed coincidences in beam pulse j associated with a trigger whose true coincidence was actually in pulse i.

- *simple assumption* $A_i = D_{ij}$ *requires the* $\langle N_{ij}^2 \rangle = \langle N_i\, N_j \rangle$, $i \neq j$

Tagger accidentals: *derivation*

- *But isn't CEBAF supposed to have duty factor = 1?*

$$f_D = \frac{<I>^2}{<I^2>} = \frac{\langle N_i\ N_j \rangle}{\langle N_i^2 \rangle}$$

- $f_D \leq 1$, can very depending on conditions at the source.
- $f_D < 1$ is associated with flucuations in laser pulse intensity.

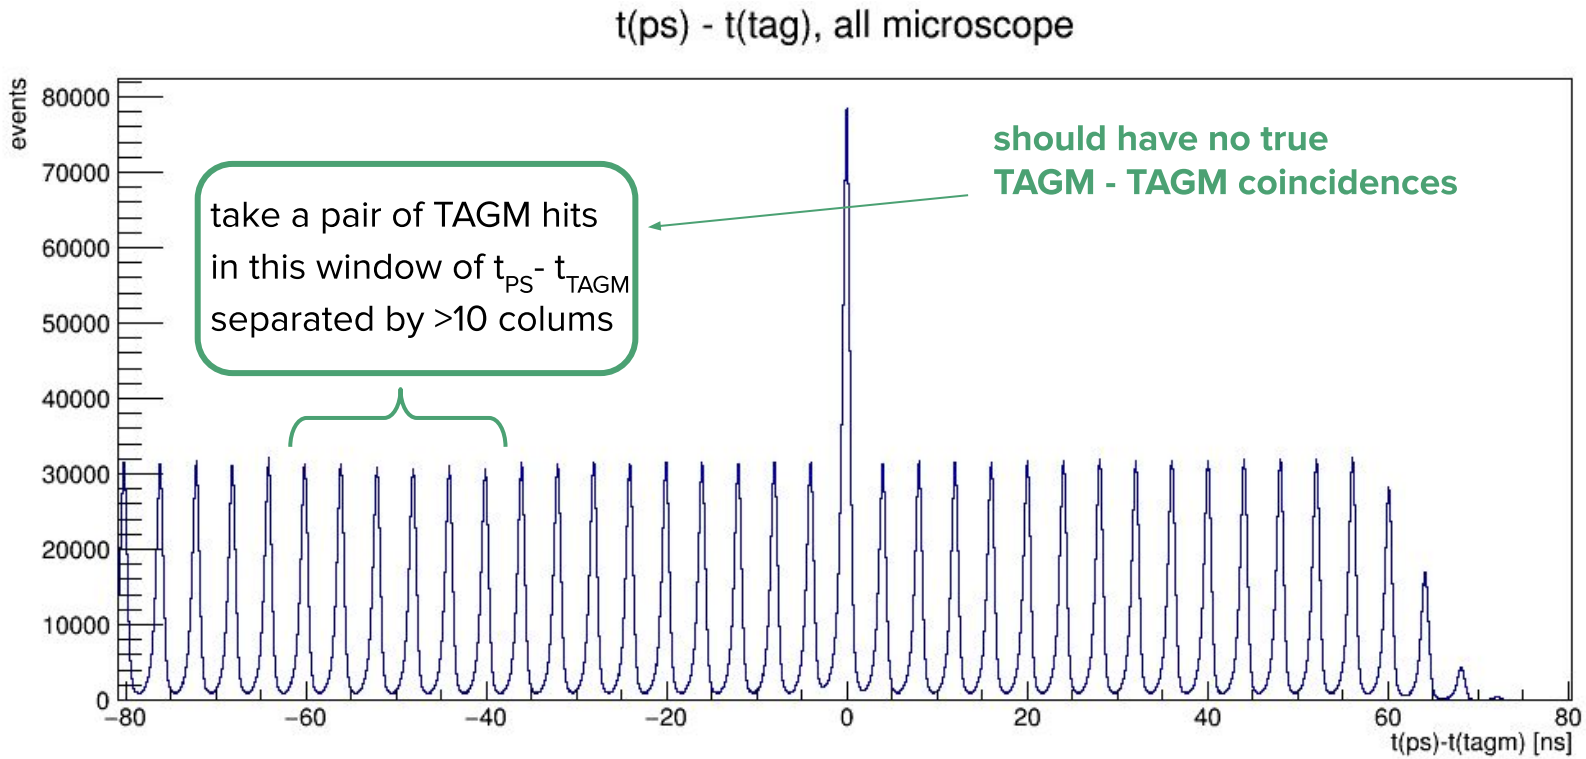
- *simple assumption* $A_i = D_{ij}$ *requires the* $<N_{ij}^2> = <N_i\ N_j>$, $i \neq j$

Tagger accidentals: *a correct prescription*

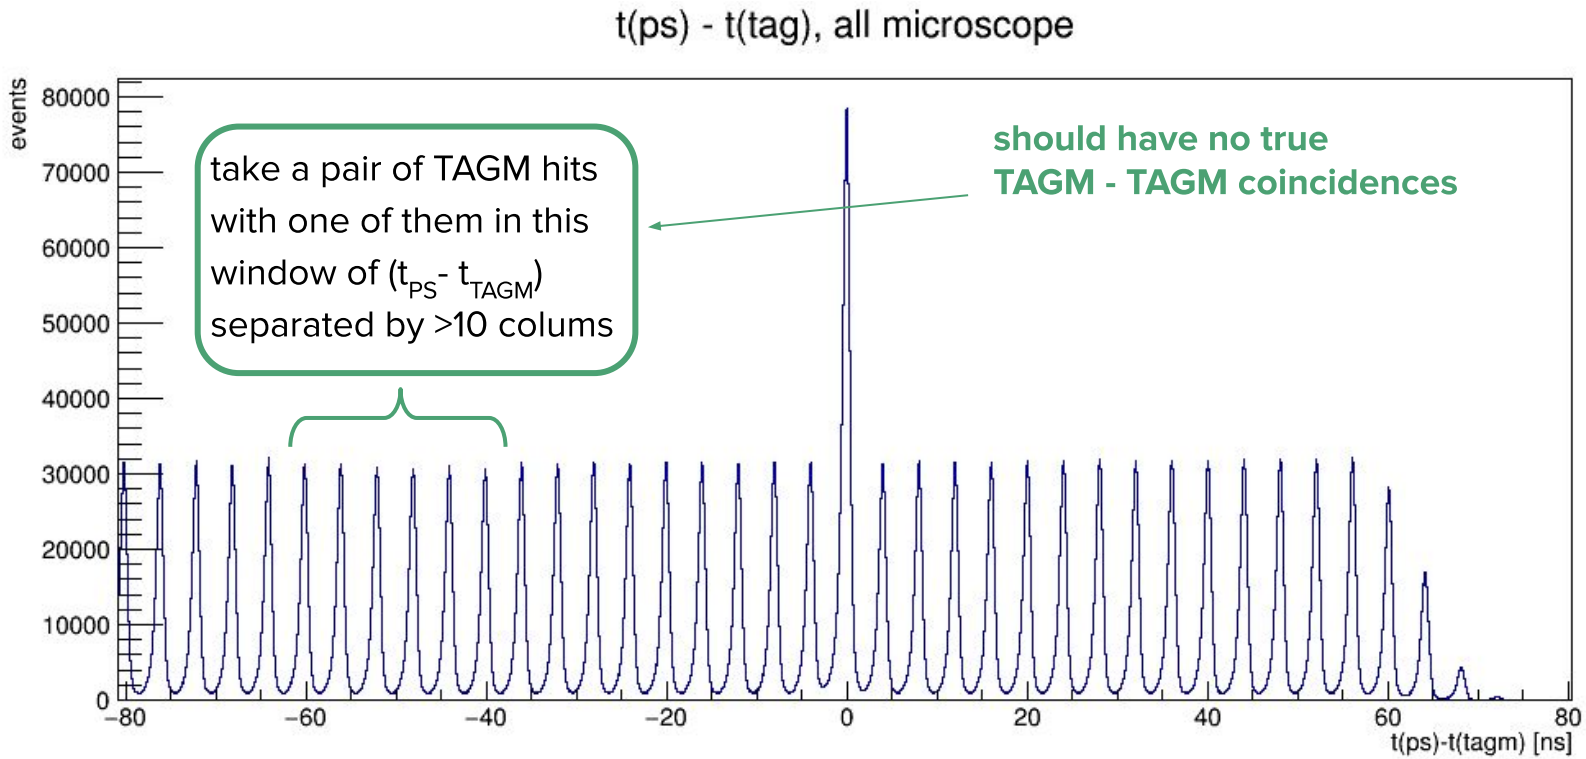
$$\hat{A}_i = \frac{1}{f_D\, S} \sum_{j=1}^{S} D_{ij}$$

- f_D should be measured using a pair of high-rate counters whose true coincidence rate can be assumed to be negligible.
- Example 1: **one tagging counter vs another tagging counter**
  - widely separated from one another on the focal plane
  - chosen such that $E_1 + E_2$ is far from the endpoint energy E_0
- Example 2: **PS coincidences vs one tagging counter**
  - chosen with E_{tag} far from $E_{\text{PSleft}} + E_{\text{PSright}}$

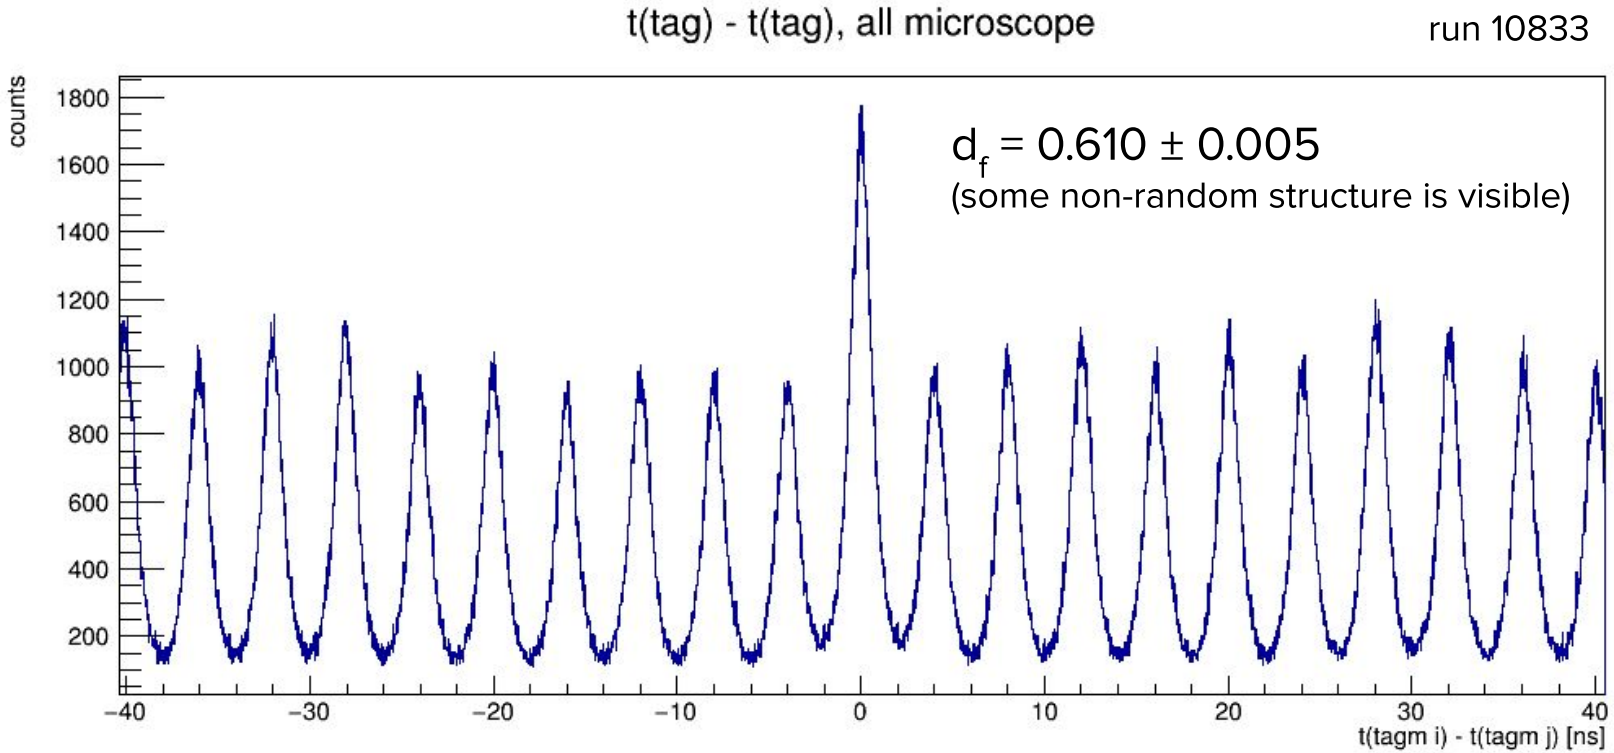
Tagger accidentals: f_D *by method 1*



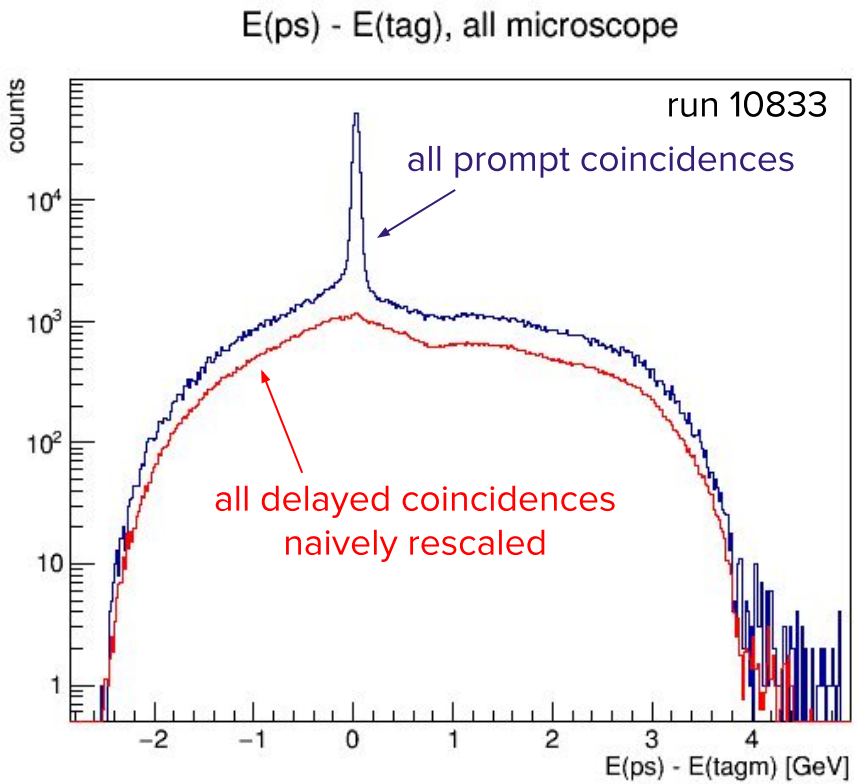
Tagger accidentals: f_D *by method 1*

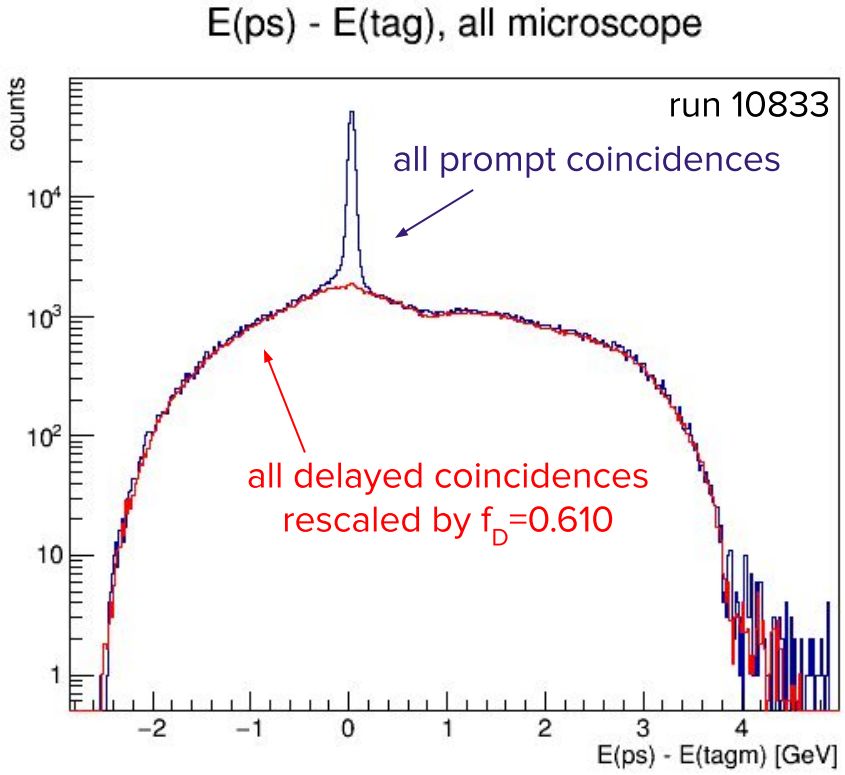


Tagger accidentals: f_D *by method 1*

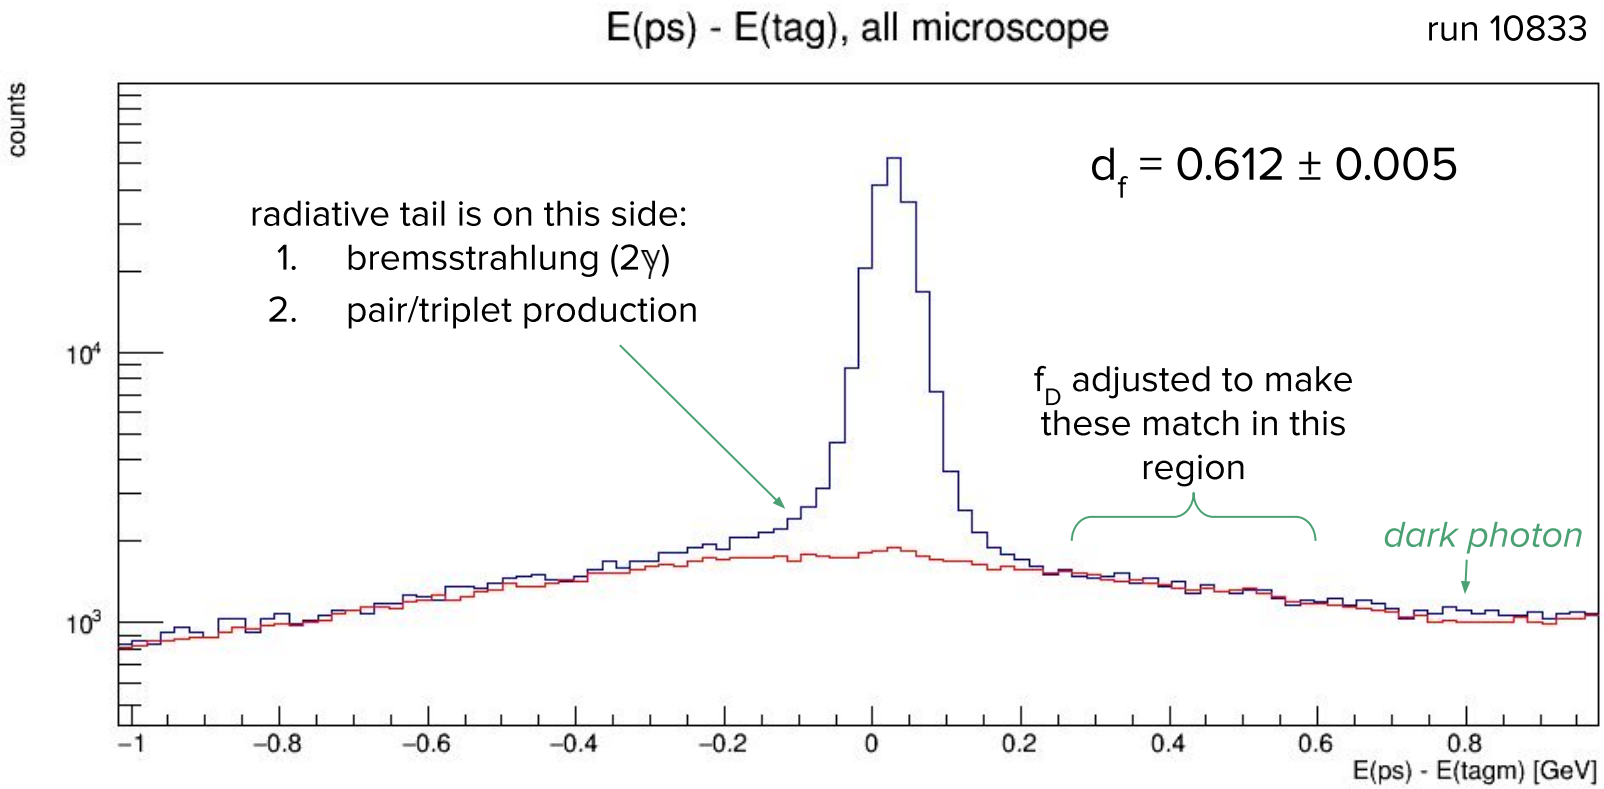


Tagger accidentals: f_D *by method 2*





Tagger accidentals: f_D by method 2

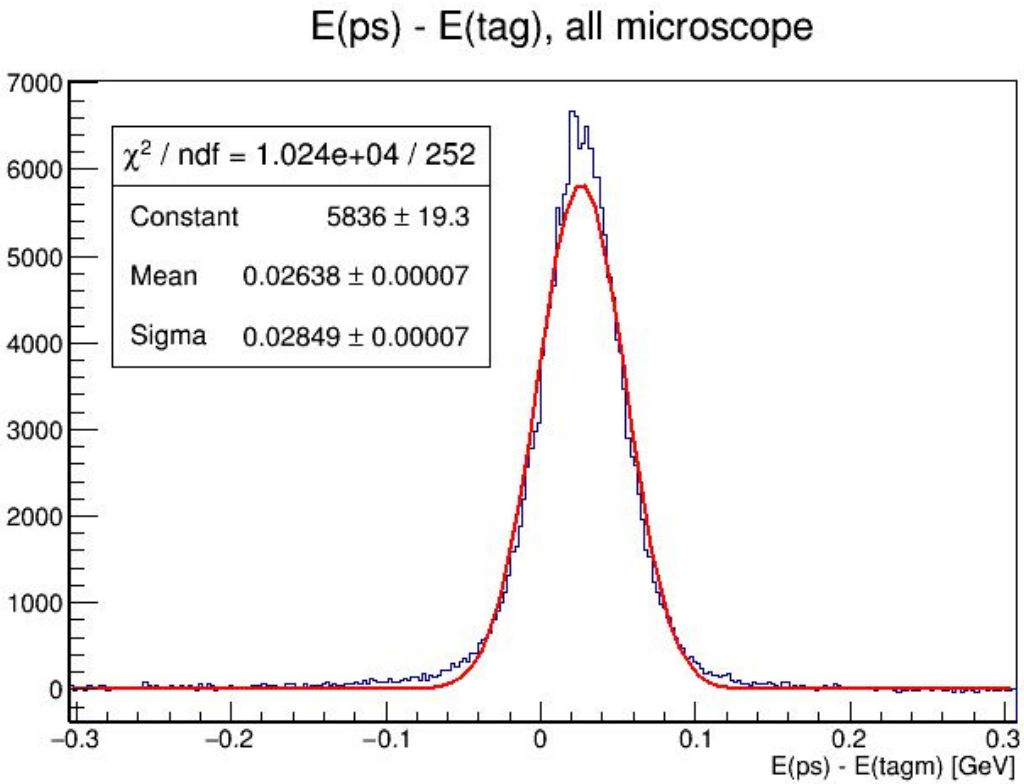


Tagger accidentals: *the path forward*

- A lot is still unknown about this:
  a. How much does f_D vary over our physics running? *probably by a lot*
  b. Does it vary signficantly within a single run period? *maybe not*
  c. Does it vary significantly with a single run? *probably not*
- Photon Beam working group will study this and issue a report within the next 3-4 weeks with a recommendation.
- At the very least we will need to:
  a. run over the existing data (PS skims) and measure f_D, save in ccdb
  b. add a watch on f_D to our online monitoring

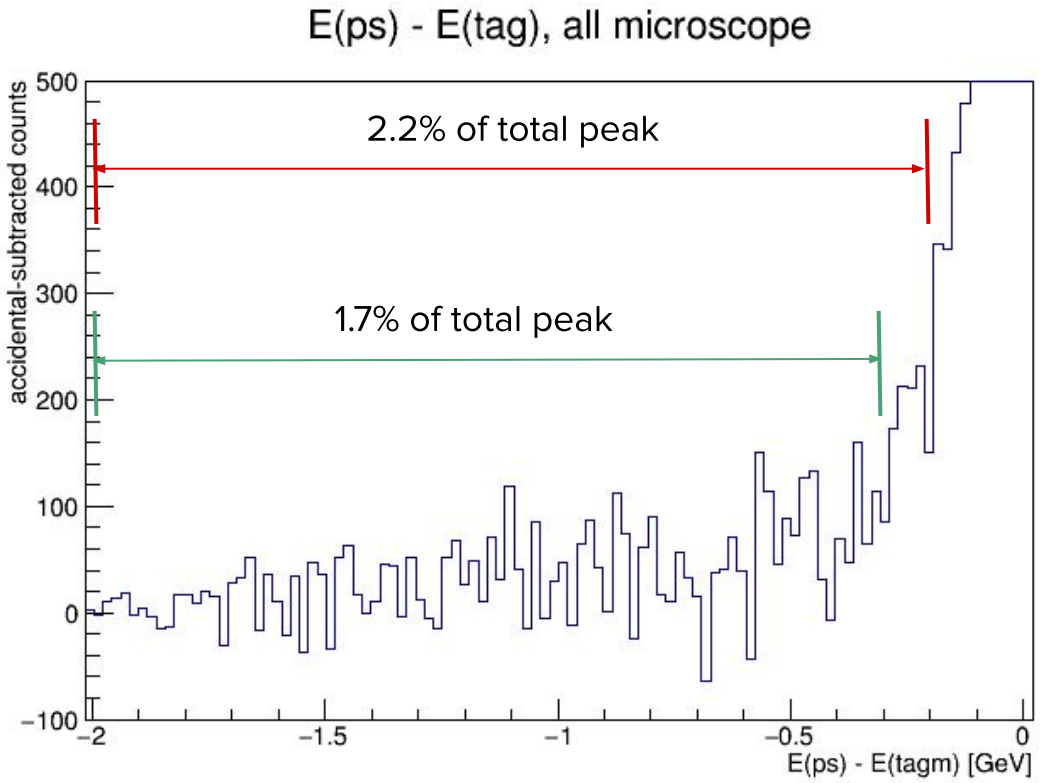
Tagger resolution

- same plot as shown before, but on a linear scale
- resolution on ΔE ~ 30 MeV is in good agreement with MC
- shift between the PS and TAGM energy scale ~25 MeV is well known, will be fixed.
- radiative tail is visible on LHS past ~100 MeV contains <1% of all PS-TAGM concidences.



Tagger resolution: *radiative tail*

- radiative tail is clearly visible past tails of the central peak ~6-7σ
- visible tail contains 2% of peak counts
- … but the tail actually goes all the way to 0 !
- radiative corrections to polarization A needed to match other sources of syst. error.



Photon beam systematics: *summary*

- PS, TAGM and TAGH energy scales need to be unified
  - plan is to use the PS simulation (uses measured map) to set the energy scale to correct the existing “scaled_energy_range” tables for TAGM/H in ccdb.
  - *RTJ will do this within next 2 weeks*

- Systematics of the dependence of the TPOL asymmetry on the E_{PS}- E_{tag} cut needs to be understood and quantified.
  - significant radiative tail is seen in the data
  - radiative correction are not presently included in MC
  - *RTJ plans to work on correcting this defect over the summer (2019).*

p.s. Diamond radiators

- **X-ray rocking curve run scheduled for June 12-14 at CLS !**
- time will be sufficient to take detailed maps of these samples:
  a. ***JD70-104*** : 17 um diamond, highest radiation damage so far
  b. ***JD70-105*** : 50 um diamond, used from spring 2017 - spring 2018
  c. ***JD70-121...125*** : 50 um diamonds, 5 new virgin samples
- these 5 new radiators are needed for our program through fall, 2020
- conservative estimate: 3-5 radiators per calendar year for 2021+
- to be understood: *character of radiation damage, possibility of annealing to recycle used radiators.*
