

Selected Light Meson Results from GlueX

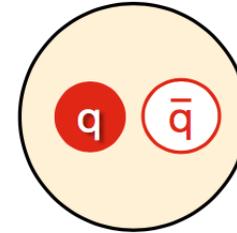

D. Mack, TJNAF
for the GlueX Collaboration
August 18, 2019 16:15

Overview

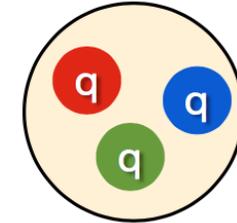

- GlueX principal motivation: hybrid meson searches
- Synergies with light meson studies ($< 1.05 \text{ GeV}/c^2$)
- Beam asymmetry Σ measurements of π^0 , η , and η' photo-production
- Spin Density Matrix Element (SDME) measurements of vector meson photo-production

GlueX Principal Motivation

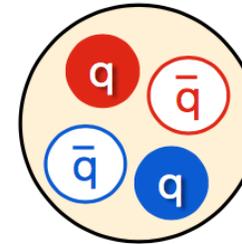

- Idea: study QCD through spectrum of bound states
 - Static properties of known hadrons well described by first- principals calculations
 - Modern experiments provide wealth of data to push boundaries of our knowledge
- Open questions:
 - What is the origin of confinement?
 - Which color-singlet states exist in nature?

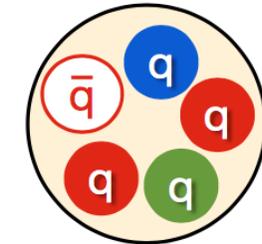

mesons

baryons

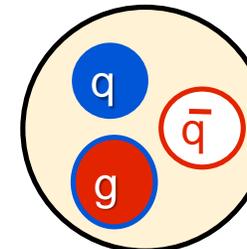

tetraquark

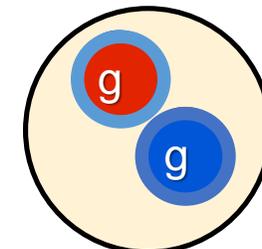

pentaquark

- **Do gluonic degrees of freedom manifest themselves in the bound states that we observe?**

hybrid meson

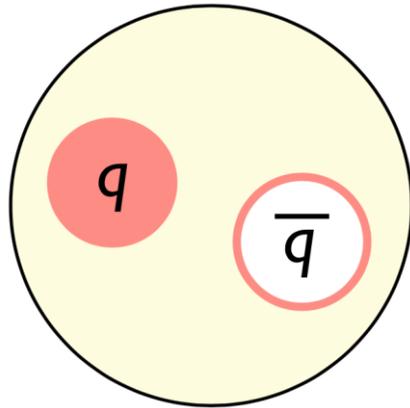

glueball

Search Filter for Hybrid Mesons: "Exotic" Quantum Numbers

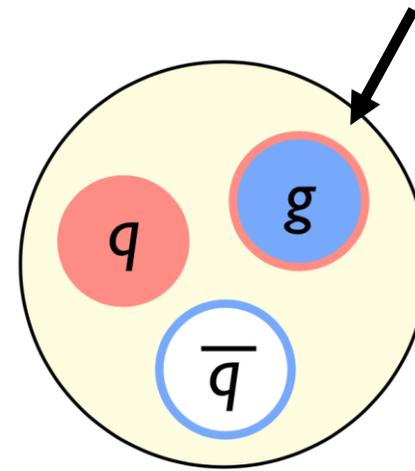

Mesons are arranged in groups of 9 ("nonets") with same J^{PC}

$$J=L+S \quad P=(-1)^{L+1} \quad C=(-1)^{L+S}$$

"Normal" Meson

gluonic field excitation \rightarrow
"constituent gluon" (J^{PC}) = 1^{+-}

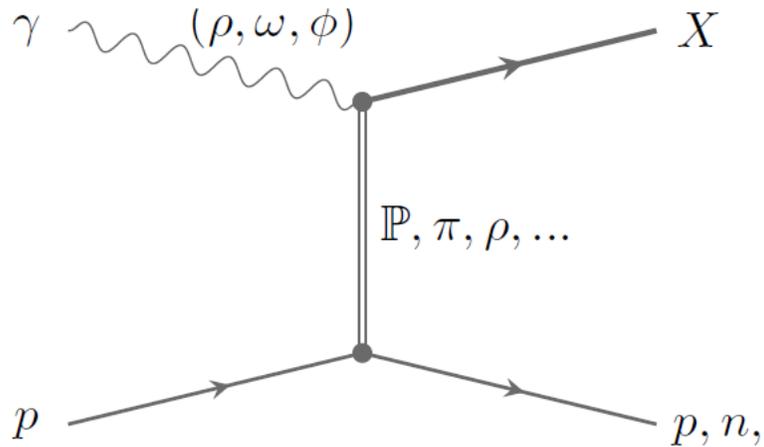

"Hybrid" Meson

Allowed J^{PC} : $0^{-+}, 0^{++}, 1^{--}, 1^{+-}, 2^{++}, 2^{-+}, \dots$ Allowed J^{PC} : $0^{-+}, 0^{+-}, 1^{--}, 1^{-+}, 2^{-+}, 2^{+-}, \dots$

Forbidden J^{PC} : $0^{--}, 0^{+-}, 1^{-+}, 2^{++}, \dots$

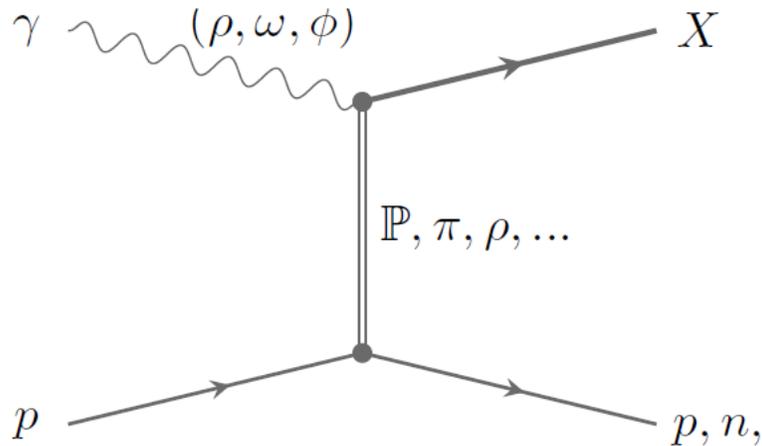

Mesons with exotic quantum numbers of $0^{+-}, 1^{-+}, 2^{+-}$ would be suggestive of constituent gluon content.
From LQCD, nominal hybrid mass search range is $1.5 - 2.5 \text{ GeV}/c^2$.

Hybrid Meson Production Via Photo-production

- A wide variety of $I^G J^{PC}$ states can be produced, including all expected hybrids.
- Existing relevant photo-production data are sparse. Barely explored territory.
- Photon polarization provides an additional constraint on the production mechanism.
- A broad survey requires a large acceptance detector with good PID for both charged particles and photons.

Exotic Meson Production Via Photo-production

- A wide variety of $I^G J^{PC}$ states can be produced, including all expected hybrids.
- Existing relevant photo-production data are sparse. Barely explored territory.
- Photon polarization provides an additional constraint on the production mechanism.
- **A broad survey requires a large acceptance detector with good PID for both charged particles and photons.**

Exchange		Exotic Final States	
\mathbb{P}	0^{++}	b, h, h'	$2^{+-}, 0^{+-}$
π^0	0^{-+}	b_2, h_2, h'_2	2^{+-}
π^\pm	0^{-+}	π_1^\pm	1^{-+}
ω	1^{--}	π_1, η_1, η'_1	1^{-+}

$$\pi_1 \rightarrow \pi\rho, \pi b_1, \pi f_1, \pi\eta', \eta a_1$$

$$\eta_1 \rightarrow \eta f_2, a_2\pi, \eta f_1, \eta\eta', \pi(1300)\pi, a_1\pi,$$

$$\eta'_1 \rightarrow K^*K, K_1(1270)K, K_1(1410)K, \eta\eta'$$

$$b_2 \rightarrow \omega\pi, a_2\pi, \rho\eta, f_1\rho, a_1\pi, h_1\pi, b_1\eta$$

$$h_2 \rightarrow \rho\pi, b_1\pi, \omega\eta, f_1\omega$$

$$h'_2 \rightarrow K_1(1270)K, K_1(1410)K, K_2^*K, \phi\eta, f_1\phi$$

$$b_0 \rightarrow \pi(1300)\pi, h_1\pi, f_1\rho, b_1\eta$$

$$h_0 \rightarrow b_1\pi, h_1\eta$$

$$h'_0 \rightarrow K_1(1270)K, K(1460)K, h_1\eta$$

Synergy Between Light Meson Studies and Exotic Hybrid Search

Consider the $\eta' \rightarrow \eta \pi^+ \pi^- \rightarrow 2\gamma \pi^+ \pi^-$ branch for which I'll show Σ asymmetry results today.

The exotic hybrid meson candidate η_1 is expected to decay as

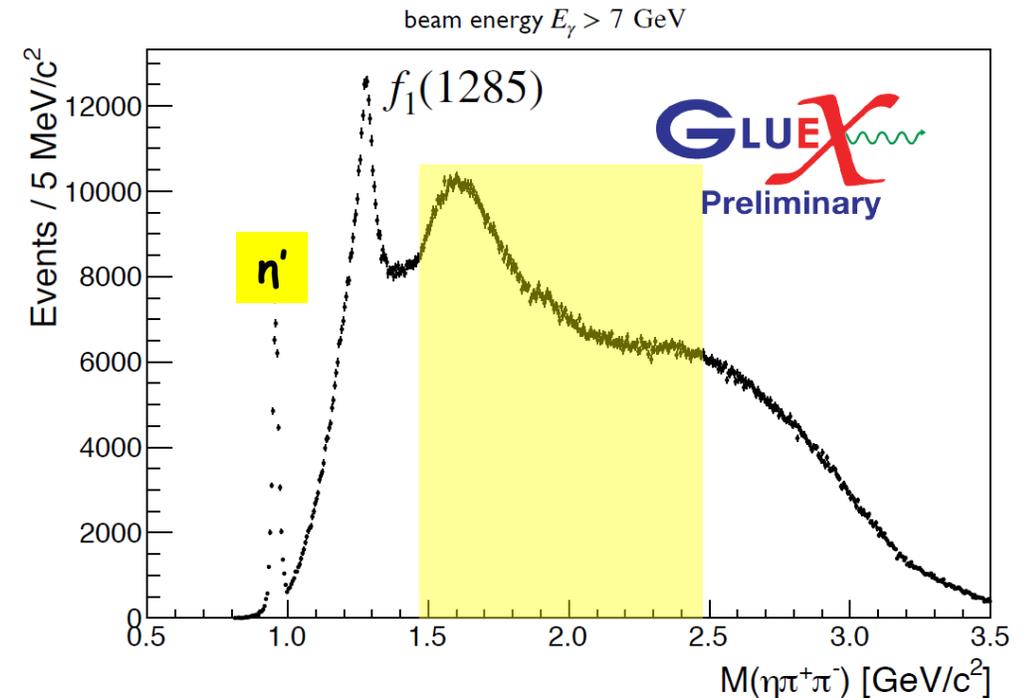

$$\begin{aligned} \eta_1 &\rightarrow \eta f_2 \rightarrow \eta (2\pi) \quad 84\% \\ &\rightarrow \pi a_2 \rightarrow \pi (\eta\pi) \quad 15\% \end{aligned}$$

where both $\eta 2\pi^0$ and $\eta \pi^+ \pi^-$ can be searched for signals.

As for the potential exotic hybrid meson b_2

$$b_2 \rightarrow \eta \rho \rightarrow \eta (\pi^+ \pi^-) \quad 100\%$$

(in this case, there is no neutral channel since no $\rho \rightarrow 2\pi^0$.)

Synergy Between Light Meson Studies and Exotic Hybrid Search

Consider the $\eta' \rightarrow \eta \pi^+ \pi^- \rightarrow 2\gamma \pi^+ \pi^-$ branch for which I'll show Σ asymmetry results today.

The exotic hybrid meson candidate η_1 is expected to decay as

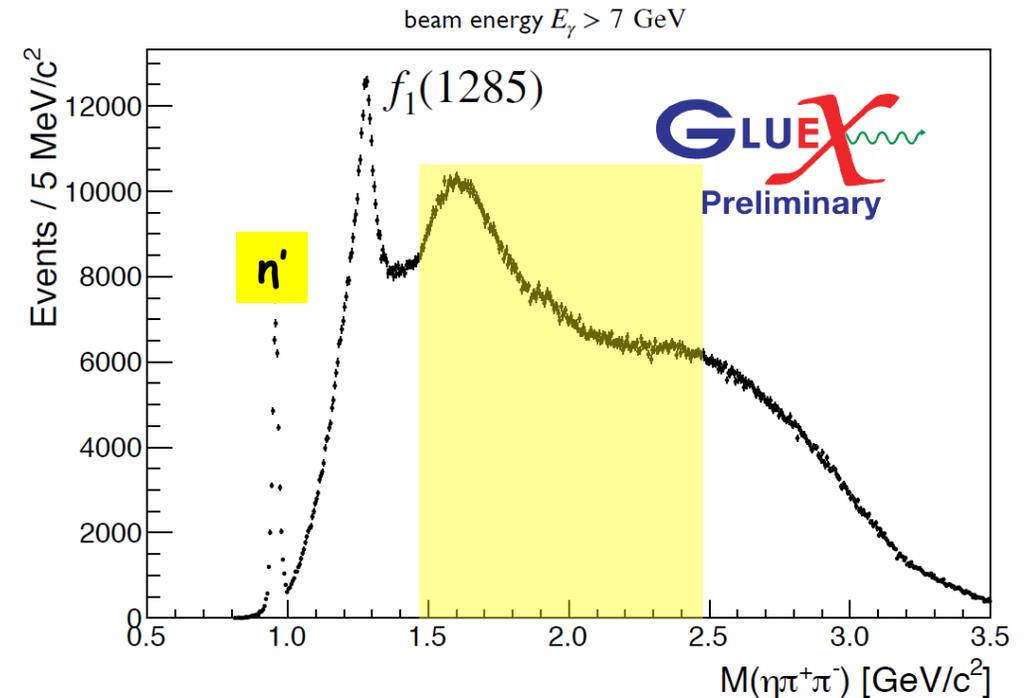

$$\begin{aligned} \eta_1 &\rightarrow \eta f_2 \rightarrow \eta (2\pi) \text{ 84\%} \\ &\rightarrow \pi a_2 \rightarrow \pi (\eta\pi) \text{ 15\%} \end{aligned}$$

where both $\eta 2\pi^0$ and $\eta \pi^+ \pi^-$ can be searched for signals.

As for the potential exotic hybrid meson b_2

$$b_2 \rightarrow \eta \rho \rightarrow \eta (\pi^+ \pi^-) \text{ 100\%}$$

(in this case, there is no neutral channel since no $\rho \rightarrow 2\pi^0$.)

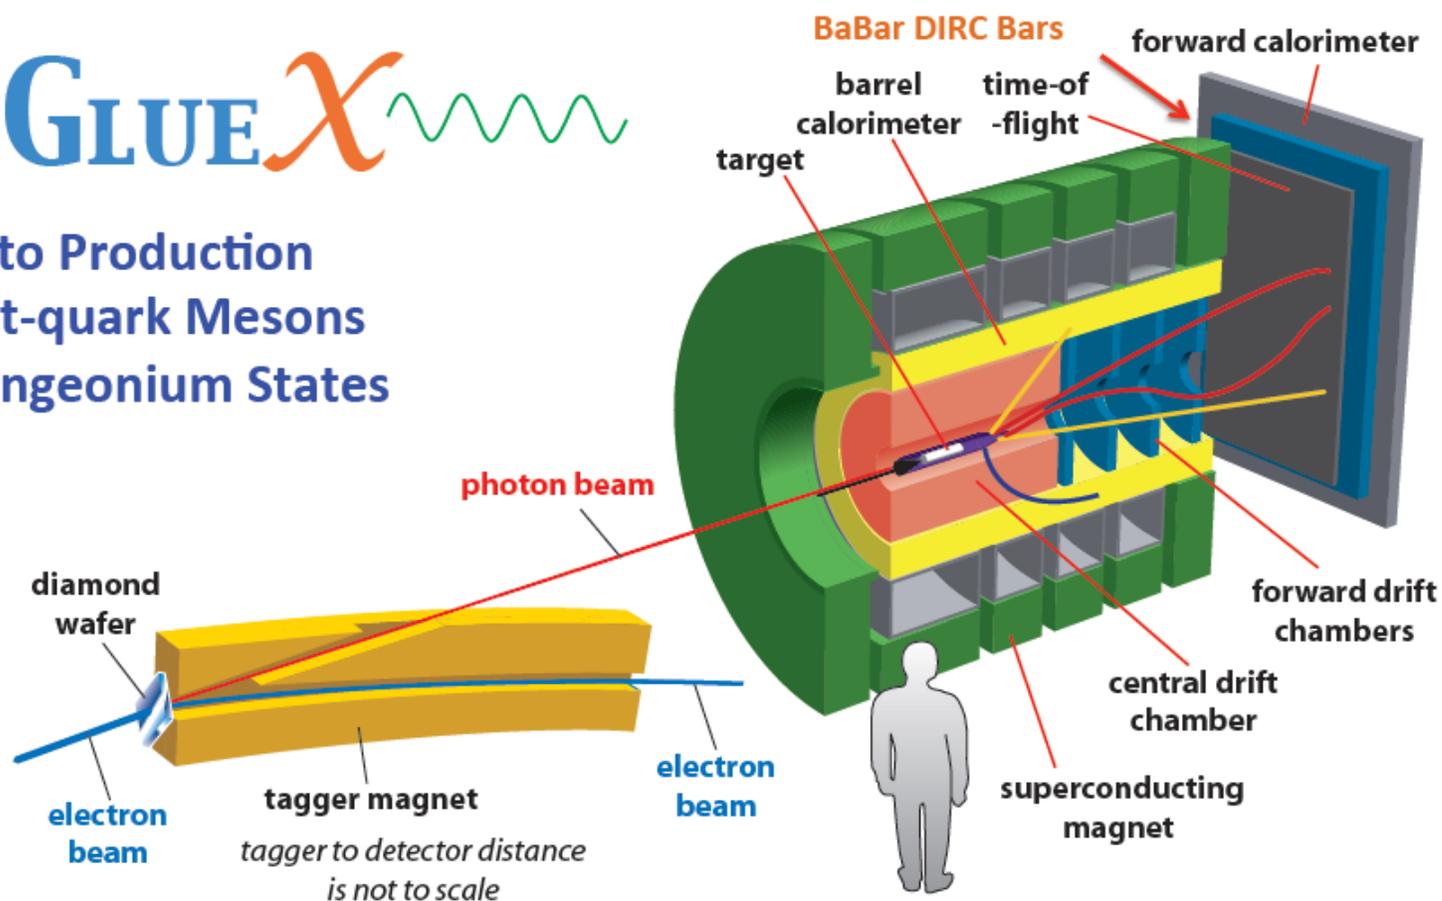

- Σ asymmetry studies of $\eta^{(\prime)}$ production have allowed us to develop cuts and study backgrounds while surveying higher masses.
- SDME studies of the vector mesons ρ , ω , and ϕ , as well as cross-section studies, are testing our acceptance corrections.
- The building blocks for nearly all the hybrid meson candidates on the previous slide have now been studied in GlueX.

The GlueX Experiment at Jefferson Lab

GLUEX

Photo Production
Light-quark Mesons
Strangeonium States

Salient features for the field of meson spectroscopy:

- Intense beam of 3-12 GeV photons of known energy
- 40% linear polarization in the coherent peak near 9 GeV.

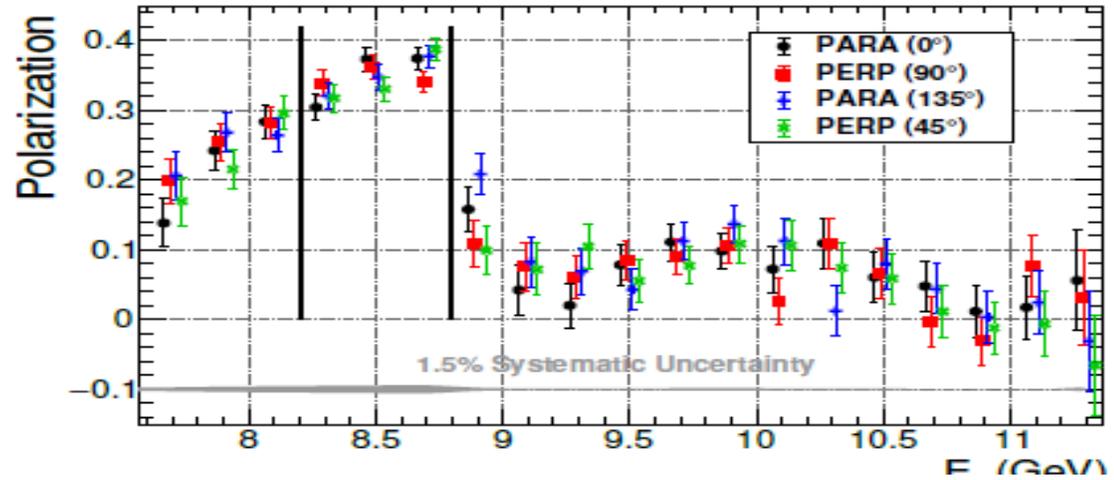

Sparse bubble chamber data from SLAC were all that existed for photons of this energy.

Polarimetry, Flux, and $W = \sqrt{s}$

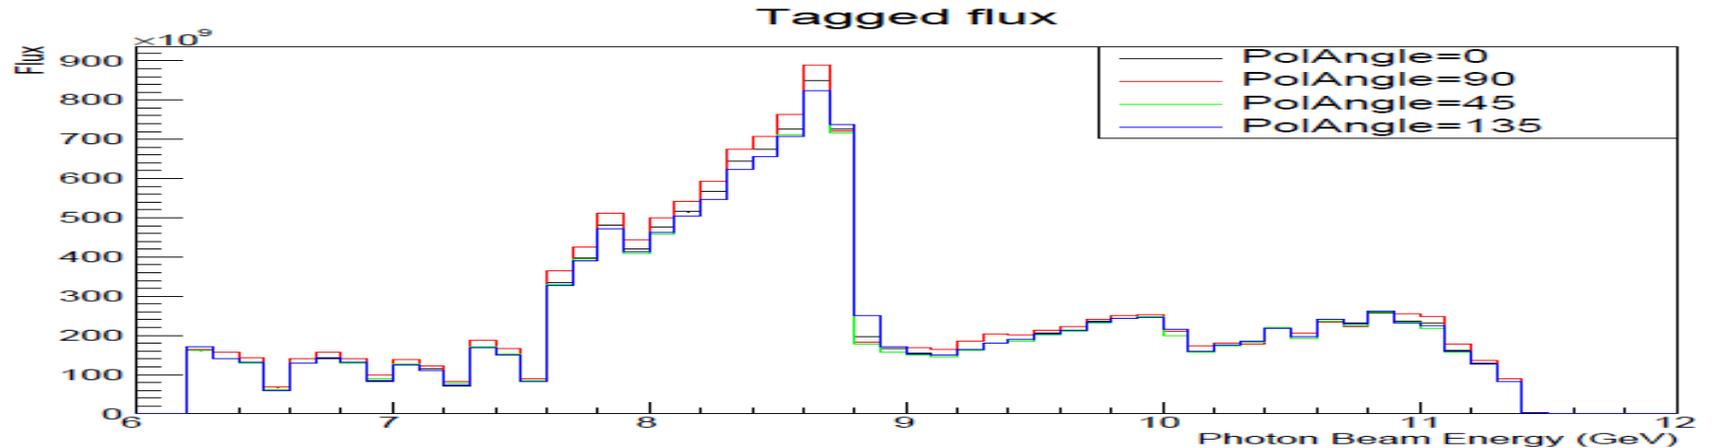

Using oriented diamond radiator, the peak polarization is near 40%.

Precision beam polarimetry ($\pm 1.5\%$ uncertainty) is provided by the Triplet POLarmeter (TPOL):

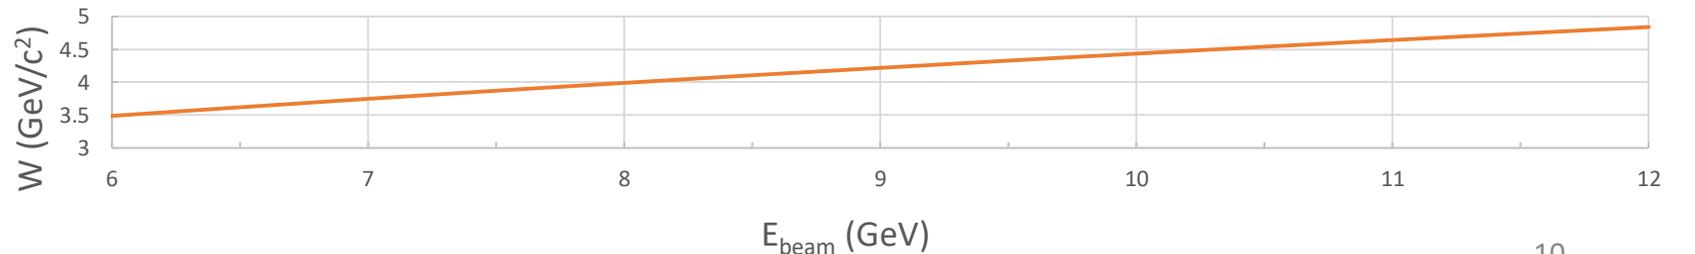

NIM A867 (2017) 115-127 <https://arxiv.org/abs/1703.07875>

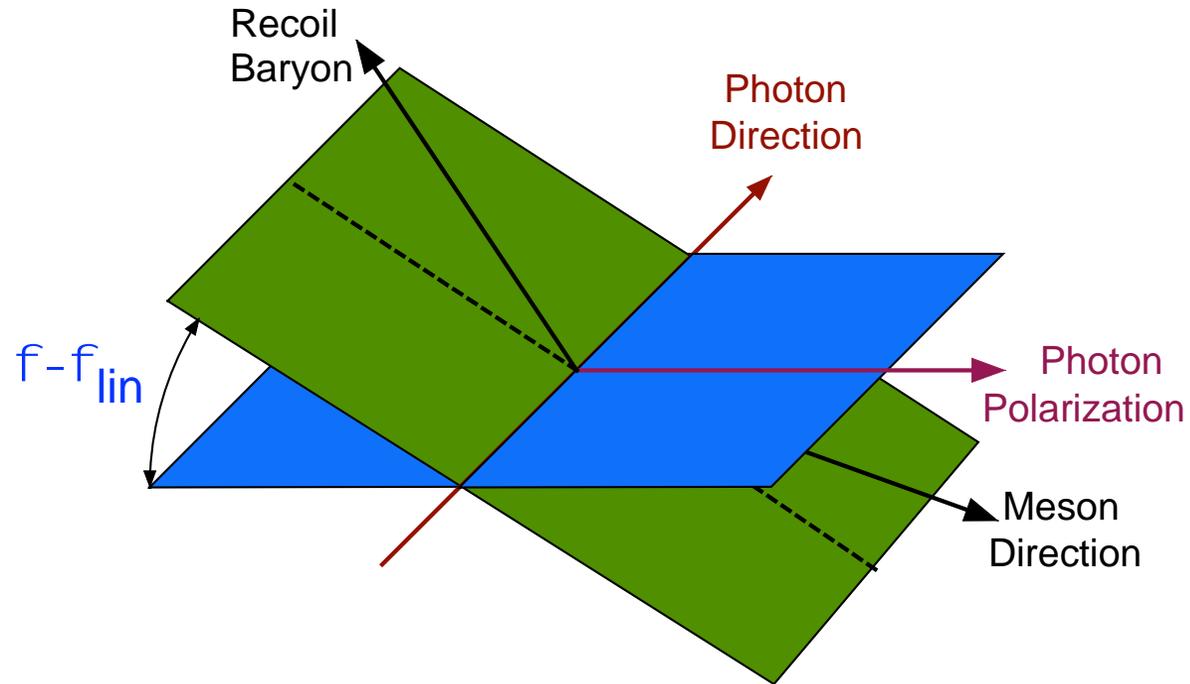

Flux also peaks near 8.8 GeV.

In the coherent peak, $W = \sqrt{s} \sim 4 \text{ GeV}/c^2$, well above the baryon resonance region.

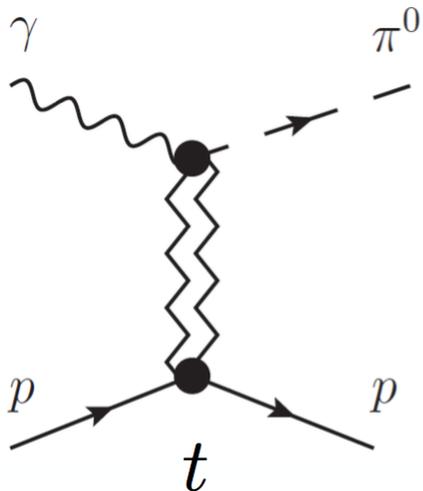

The Beam Asymmetry, Σ , for $\gamma+p \rightarrow p+PS$
Tests the reaction mechanism for photo-production.

See also W. McGinley and T. Beattie, MENU 2019: <https://registration.mcs.cmu.edu/event/1/contributions/145/>

Beam Asymmetries: $\gamma + p \rightarrow p + \pi^0 / \eta^{(\prime)}$

- Aids in understanding the reaction mechanism for photo-production of pseudo-scalar mesons.
- "Production of the lightest multiplet of exotic mesons with $J^{PC} = 1^{-+}$ involves the same Regge exchanges that appear in the production of ordinary pseudoscalar mesons, like π^0 , η , and η' ." <https://arxiv.org/abs/1704.07684v2>
- Understanding the production mechanisms will assist in building a hybrid PWA model to describe the data.
- Through Finite Energy Sum Rules, data at high energy described by exchange of meson Regge poles can constrain models at lower energy in the baryon resonance region. <https://arxiv.org/abs/1708.07779>

Exchange J^{PC}

$1^{--} : \omega, \rho$

$1^{+-} : b, h$

$$\Sigma = \frac{|\omega + \rho|^2 - |h + b|^2}{|\omega + \rho|^2 + |h + b|^2}$$

$\Sigma \sim 1$ means dominance of vector (natural parity) exchange.

$\Sigma \sim -1$ means dominance of axial vector (unnatural parity) exchange

Cancellation of Instrumental Asymmetries

With ϕ the angle of the meson production plane, and ϕ_s the angle in which the linear polarization lies, the ϕ dependent yield is given in terms of the cross section and the beam asymmetry, Σ :

$$Y_{\text{pol}}(\phi) = \sigma_0[1 - P\Sigma\cos\{2(\phi-\phi_s)\}]$$

In principle, for one ϕ_s setting we could fit $P\Sigma$. But there's usually a scale-type instrumental asymmetry of $O(1)\%$, so in practice

$$Y_{\text{pol}}(\phi) = \sigma_0[1 - P\Sigma\cos\{2(\phi-\phi_s)\}] A(\phi)$$

To avoid having to correct for $A(\phi)$, we combine measurements at two values of ϕ_s ,

for $\phi_s = 0^\circ$ (Parallel),
$$Y_{\text{para}}(\phi) = \sigma_0[1 - P\Sigma\cos(2\phi)] A(\phi)$$

for $\phi_s = 90^\circ$ (Perpendicular),
$$Y_{\text{perp}}(\phi) = \sigma_0[1 + P\Sigma\cos(2\phi)] A(\phi)$$

Then

$$\frac{Y_{\text{perp}}(\phi) - Y_{\text{para}}(\phi)}{Y_{\text{perp}}(\phi) + Y_{\text{para}}(\phi)} = P\Sigma\cos(2\phi)$$

which can be fitted to obtain $P\Sigma$.

Cancellation of Instrumental Asymmetries

With ϕ the angle of the meson production plane, and ϕ_s the angle in which the linear polarization lies, the ϕ dependent yield is given in terms of the cross section and the beam asymmetry, Σ :

$$Y_{\text{pol}}(\phi) = \sigma_0[1 - P\Sigma\cos\{2(\phi-\phi_s)\}]$$

In principle, for one ϕ_s setting we could fit $P\Sigma$. But there's usually a scale-type instrumental asymmetry of $O(1)\%$, so in practice

$$Y_{\text{pol}}(\phi) = \sigma_0[1 - P\Sigma\cos\{2(\phi-\phi_s)\}] A(\phi)$$

To avoid having to correct for $A(\phi)$, we combine measurements at two values of ϕ_s ,

for $\phi_s = 0^\circ$ (Parallel),

$$Y_{\text{Para}}(\phi) = \sigma_0[1 - P\Sigma\cos(2\phi)] A(\phi)$$

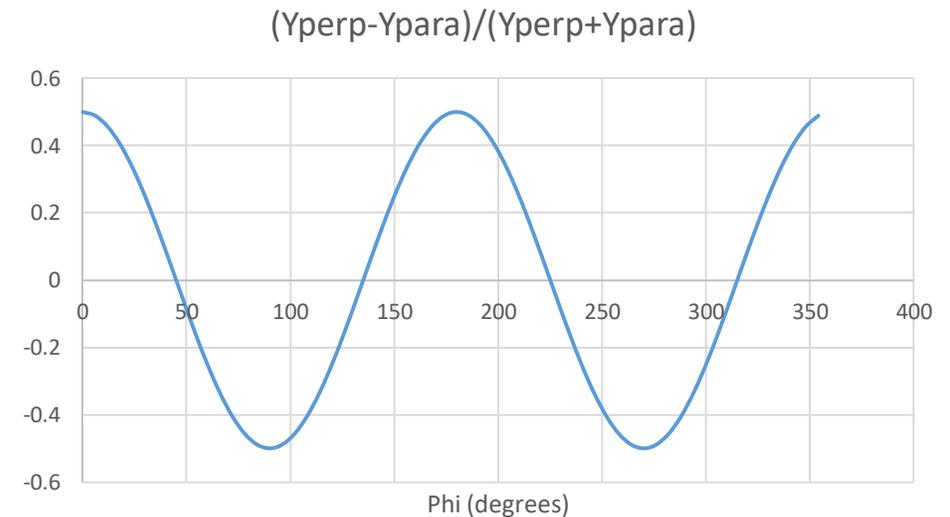

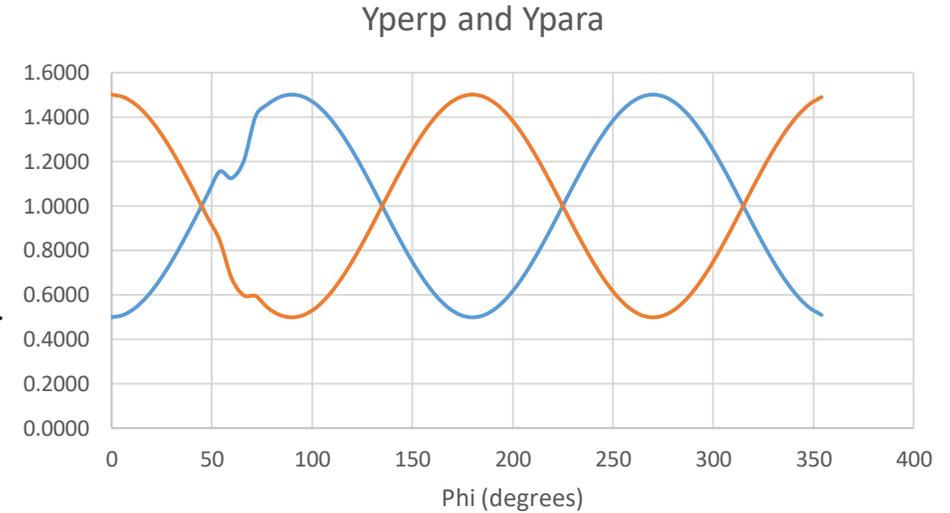

for $\phi_s = 90^\circ$ (Perpendicular),

$$Y_{\text{Perp}}(\phi) = \sigma_0[1 + P\Sigma\cos(2\phi)] A(\phi)$$

Then

$$\frac{Y_{\text{Perp}}(\phi) - Y_{\text{Para}}(\phi)}{Y_{\text{Perp}}(\phi) + Y_{\text{Para}}(\phi)} = P\Sigma\cos(2\phi)$$

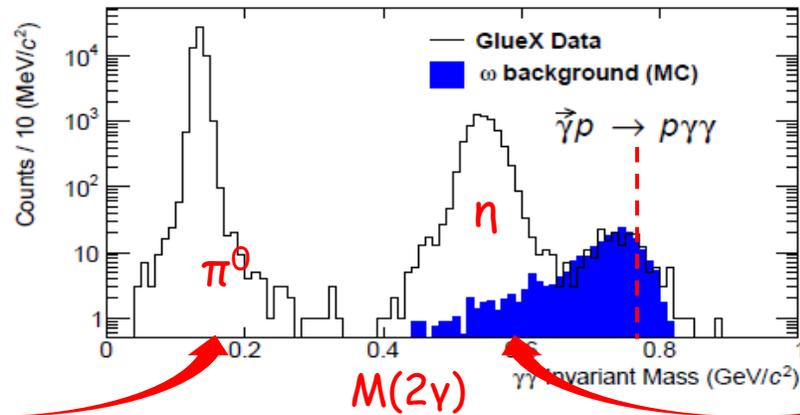

which can be fitted to obtain $P\Sigma$.

As long as the inefficiency doesn't change with time, it cancels exactly.

How the Beam Asymmetry is Measured

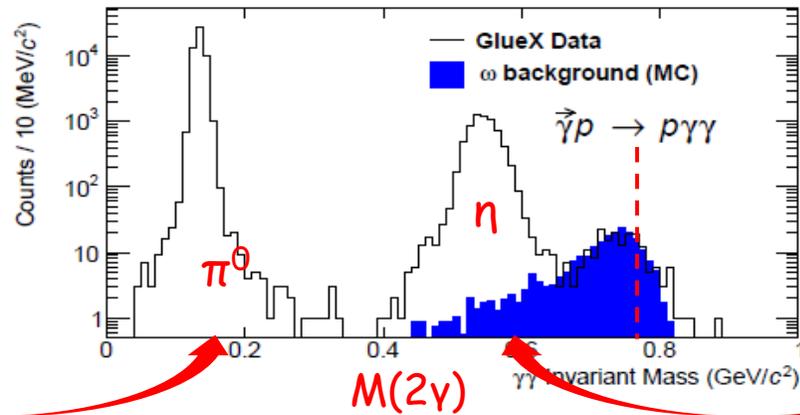

π^0 region:
negligible bkg from missing a
bachelor photon from $\omega \rightarrow \pi^0 \gamma_B$.

η region:
Small bkg from missing a
photon from the π^0 in $\omega \rightarrow \pi^0 \gamma_B$.

How the Beam Asymmetry is Measured

π^0 region:
negligible bkg from missing a bachelor photon from $\omega \rightarrow \pi^0 \gamma_B$.

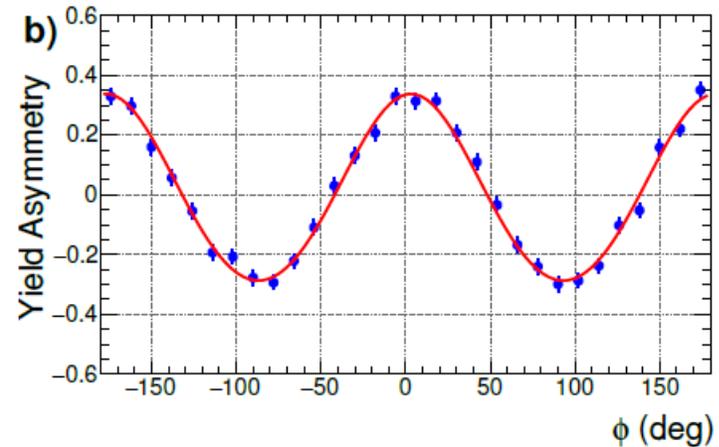

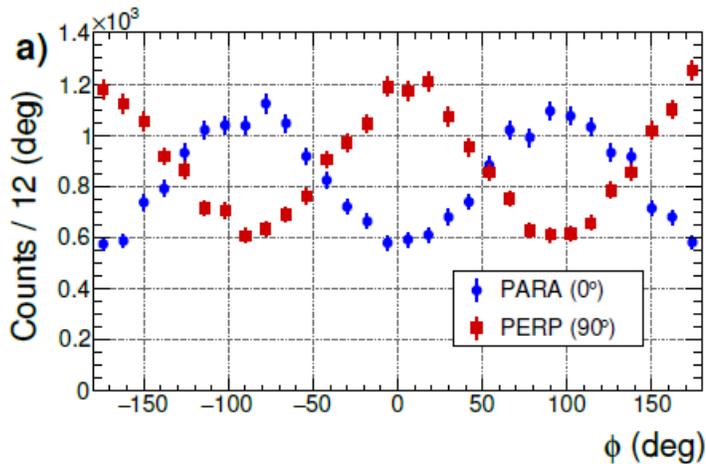

η region:
Small bkg from missing a photon from the π^0 in $\omega \rightarrow \pi^0 \gamma_B$.

$Y_{\text{perp}}(\phi)$

And

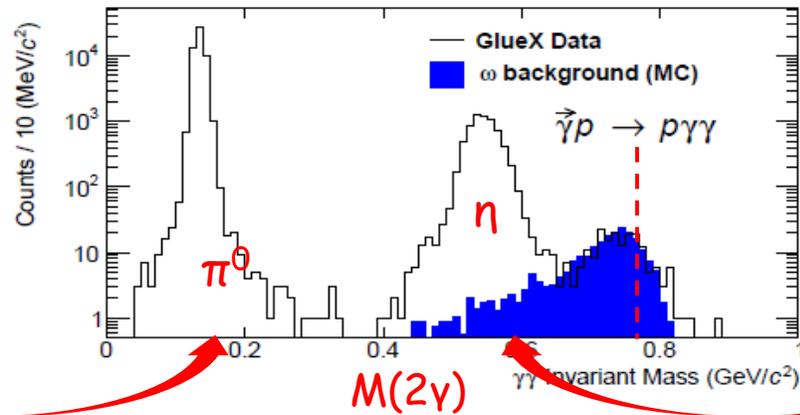

$Y_{\text{Para}}(\phi)$

$$\frac{Y_{\text{perp}}(\phi) - Y_{\text{Para}}(\phi)}{Y_{\text{perp}}(\phi) + Y_{\text{Para}}(\phi)}$$

How the Beam Asymmetry is Measured

π^0 region:
negligible bkg from missing a bachelor photon from $\omega \rightarrow \pi^0 \gamma_B$.

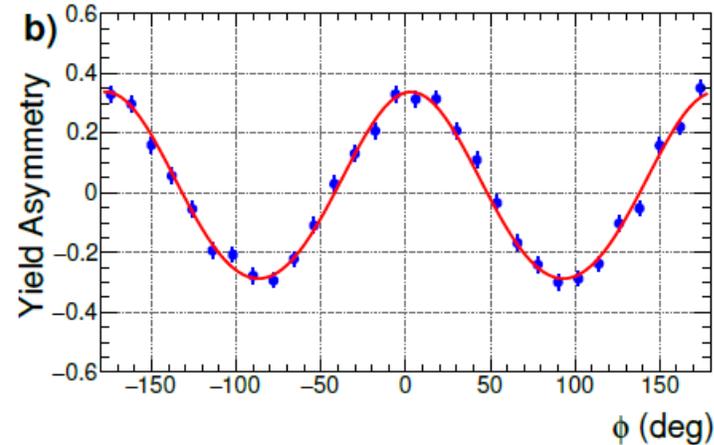

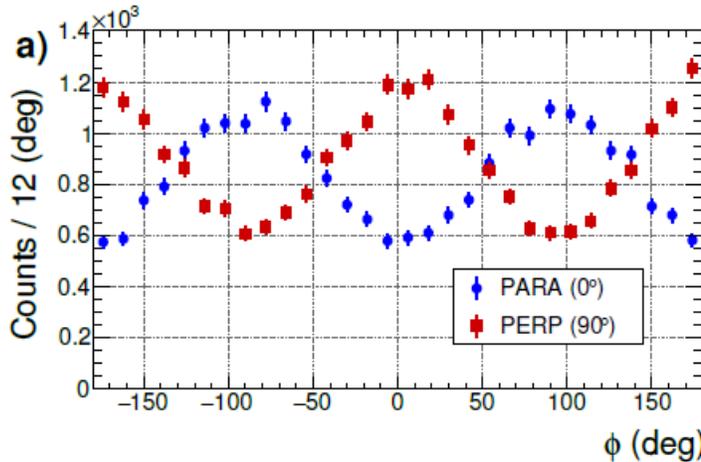

η region:
Small bkg from missing a photon from the π^0 in $\omega \rightarrow \pi^0 \gamma_B$.

$Y_{\text{perp}}(\phi)$

And

$Y_{\text{para}}(\phi)$

$$\frac{Y_{\text{perp}}(\phi) - Y_{\text{para}}(\phi)}{Y_{\text{perp}}(\phi) + Y_{\text{para}}(\phi)}$$

In practice, we fit Σ allowing for $P_{\text{perp}} \neq P_{\text{para}}$ as well as a small azimuthal offset between ϕ of the detector and ϕ_s of the diamond.

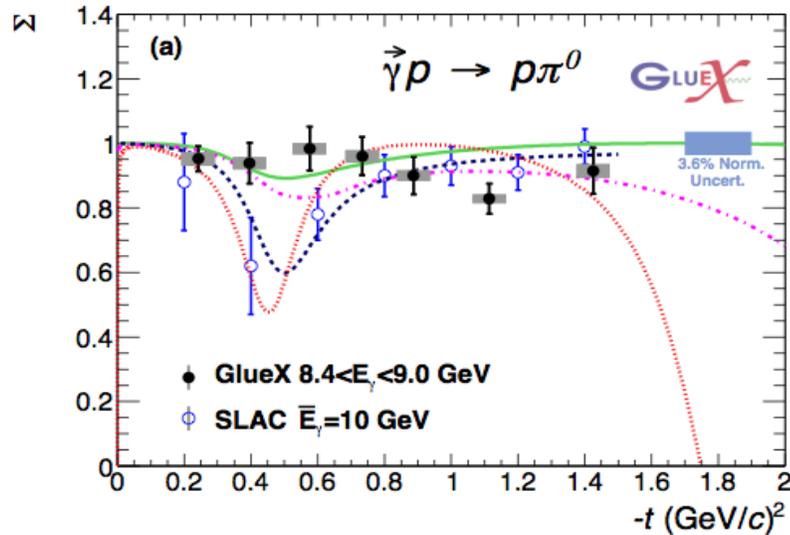

$$\frac{Y_{\text{perp}}(\phi) - Y_{\text{para}}(\phi)}{Y_{\text{perp}}(\phi) + Y_{\text{para}}(\phi)} = \frac{P_{\text{ave}} \Sigma \cos[2(\phi - \phi_0)]}{1 + \Delta P \Sigma \cos[2(\phi - \phi_0)]/2}$$

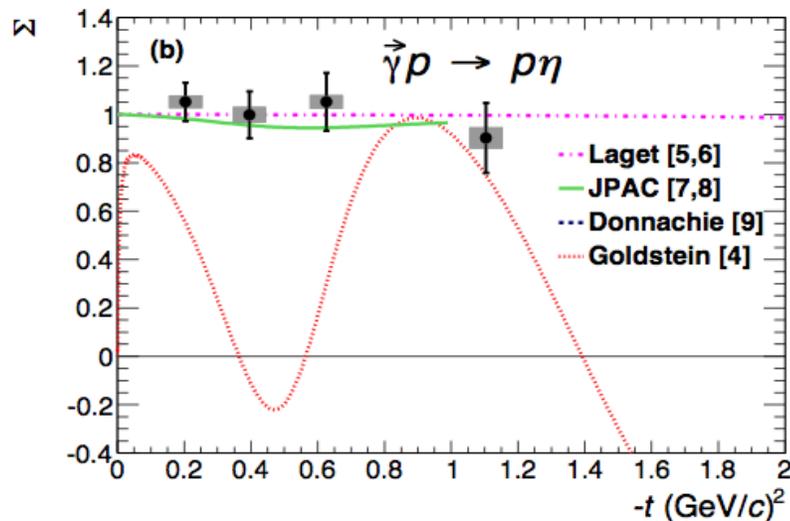

Beam Asymmetries from Commissioning Run: $\gamma + p \rightarrow p + \pi^0 / \eta$

Asymmetry Σ

Asymmetry Σ

Our first GlueX physics publication!
 PRC 95, 042201 (2017)
<https://arxiv.org/abs/1701.08123>

Sabbatical project of Zhenyu "Jane" Zhang, Wuhan U.

(Go, Wuda! You will always be "jiejie" in our GlueX family.)

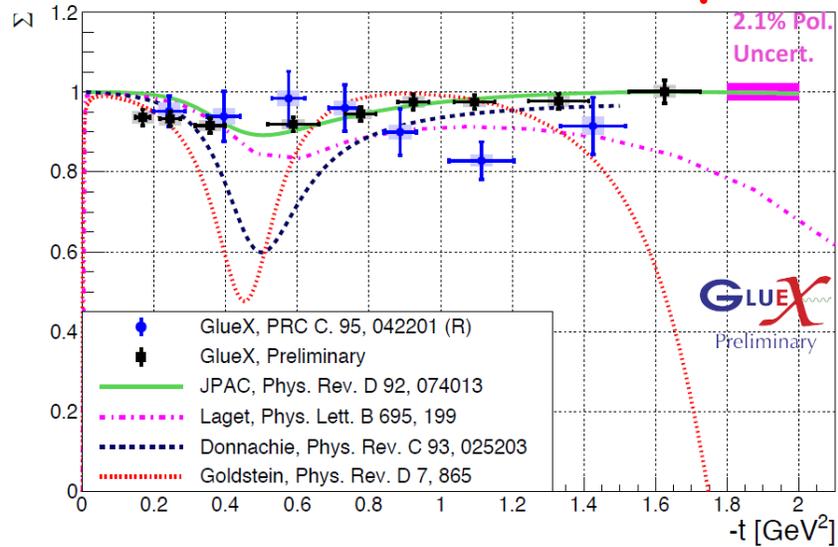

Exclusive, very low bkg measurements of $\gamma + p \rightarrow p + 2\gamma$:

- $\Sigma \approx 1$ indicated vector exchange dominates this beam energy and $-t$ range.
- The η measurement was the first in this beam energy range.

Updated Beam Asymmetries with 8x More Data:

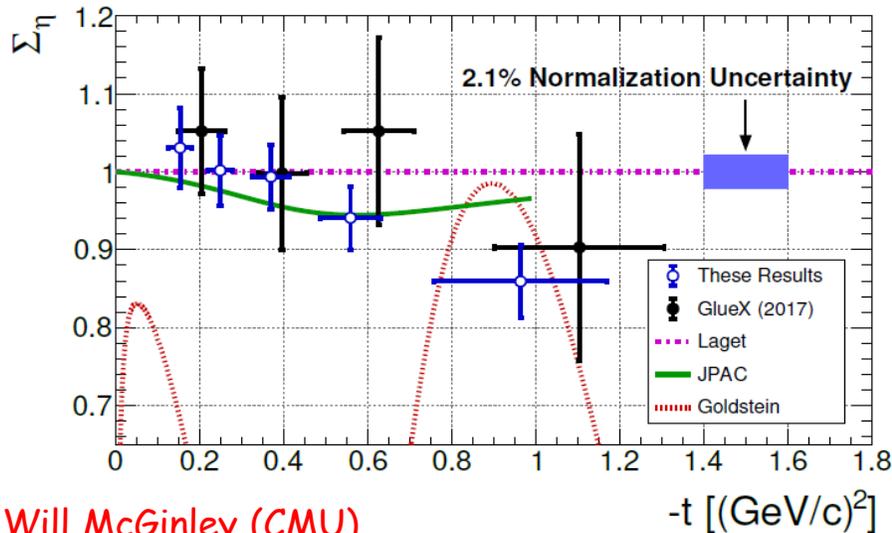

Asymmetry Σ

π^0 results have been updated (in black).

High statistics π^0 data allowed us to explore fit systematics at the sub-percent level.

Asymmetry Σ

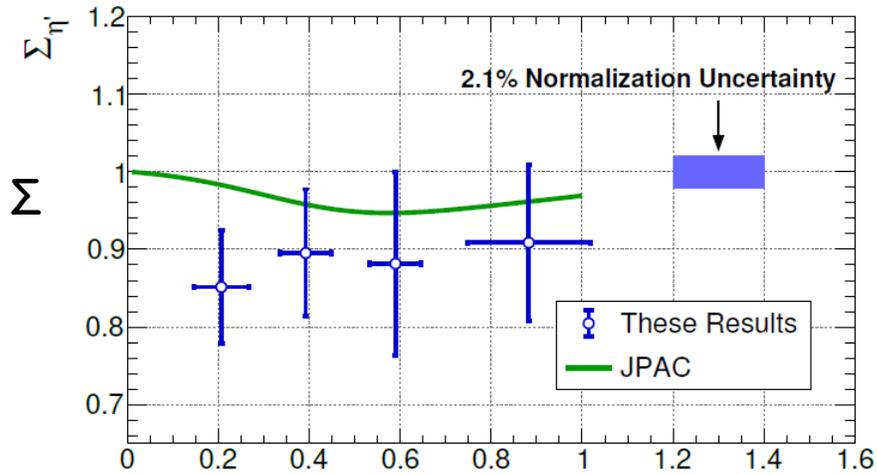

η results have been updated (in blue).

For both π^0 and η , these much more precise results elucidate the higher order contributions from axial vector meson exchange such as the b_1 .

Thesis work of Will McGinley (CMU)

Paper now submitted to PRC:
<http://arxiv.org/abs/1908.05563>

A New Beam Asymmetry for GlueX: $\gamma p \rightarrow p + \eta'$

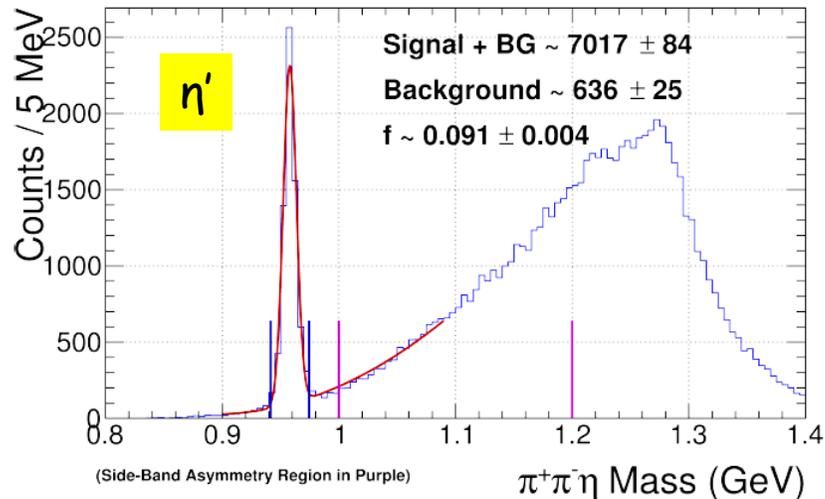

- First beam asymmetry measurements of the η' in this energy range.
- Uses our cleanest, highest yield η' channel: $\eta' \rightarrow \eta \pi^+ \pi^- \rightarrow 2\gamma \pi^+ \pi^-$
- All 5 final state particles (including the recoil proton) are detected with an acceptance of $\sim 10\%$.

With these limited η' statistics, all we can say with confidence is that the η' results are dominated by vector meson exchange.

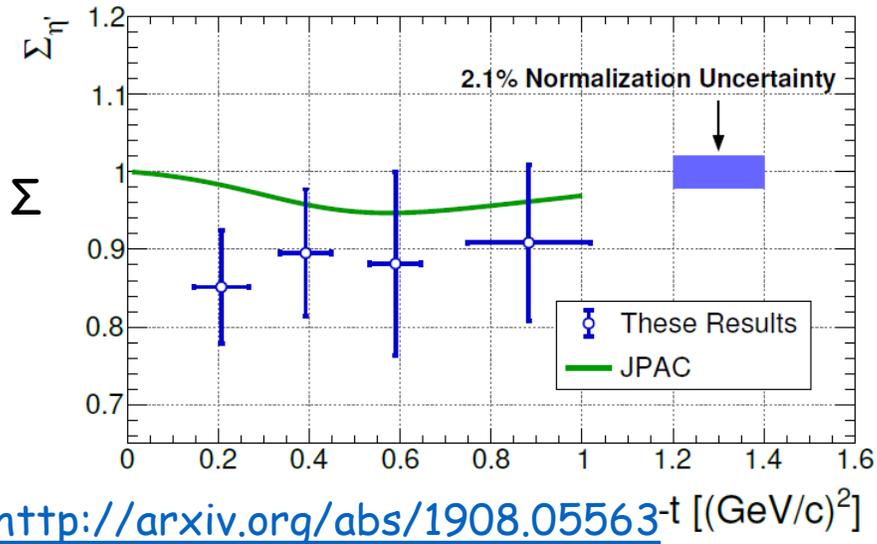

<http://arxiv.org/abs/1908.05563>^t [(GeV/c)²]

$\pi^+ \pi^- \eta$ Mass Post-Cut

Thesis topic of Tegan Beattie (U. Regina)

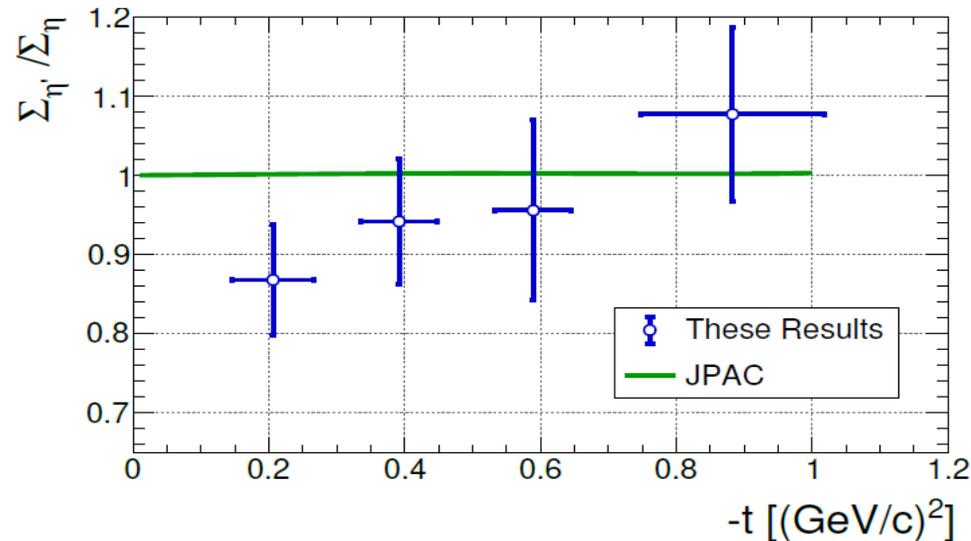

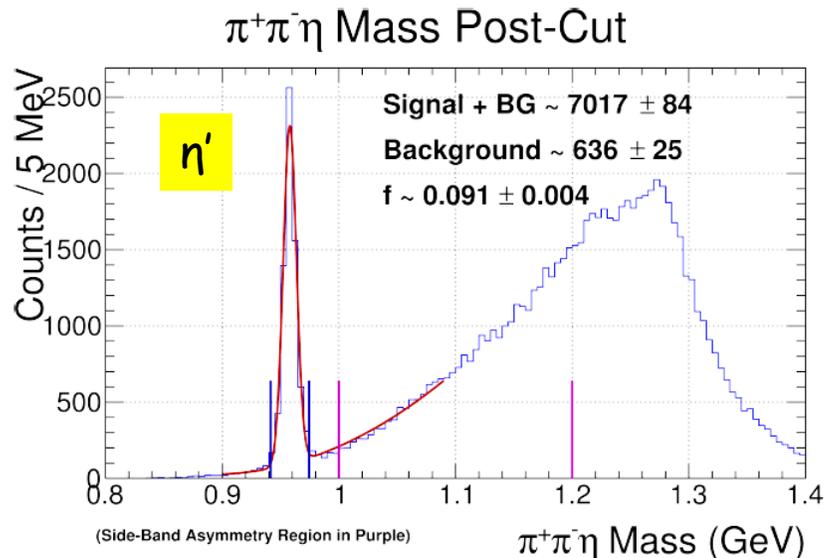

A New Beam Asymmetry for GlueX: $\gamma p \rightarrow p + \eta'$

- First beam asymmetry measurements of the η' in this energy range.
- Uses our cleanest, highest yield η' channel: $\eta' \rightarrow \eta \pi^+ \pi^- \rightarrow 2\gamma \pi^+ \pi^-$
- All 5 final state particles (including the recoil proton) are detected with an acceptance of $\sim 10\%$.

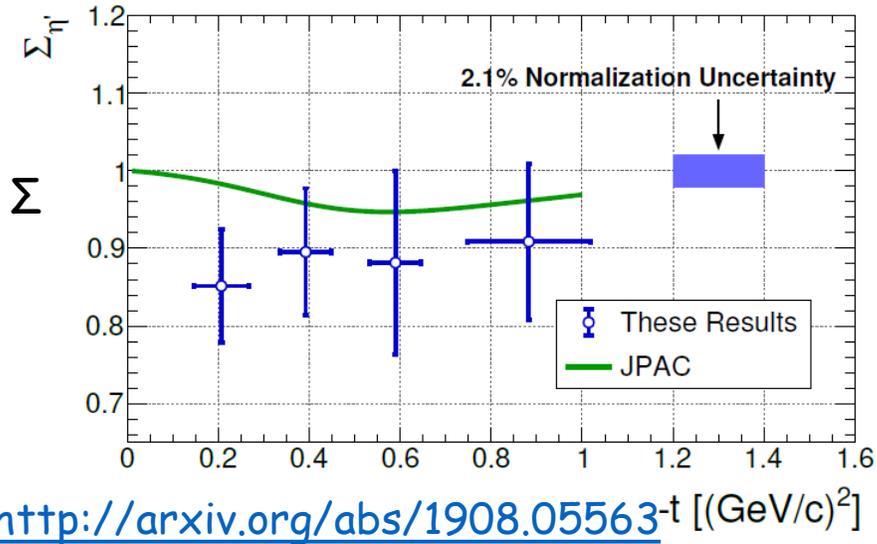

With these limited η' statistics, all we can say with confidence is that the η' results are dominated by vector meson exchange.

The ratio of η'/η asymmetries should be exactly 1 without hidden strangeness (eg, ϕ exchange). With expected levels of $N \rightarrow N\phi$, the ratio should be less 1.01 . <https://arxiv.org/abs/1704.07684>

- Uses our cleanest, highest yield η' channel: $\eta' \rightarrow \eta \pi^+ \pi^- \rightarrow 2\gamma \pi^+ \pi^-$
- All 5 final state particles (including the recoil proton) are detected with an acceptance of $\sim 10\%$.

With these limited η' statistics, all we can say with confidence is that the η' results are dominated by vector meson exchange.

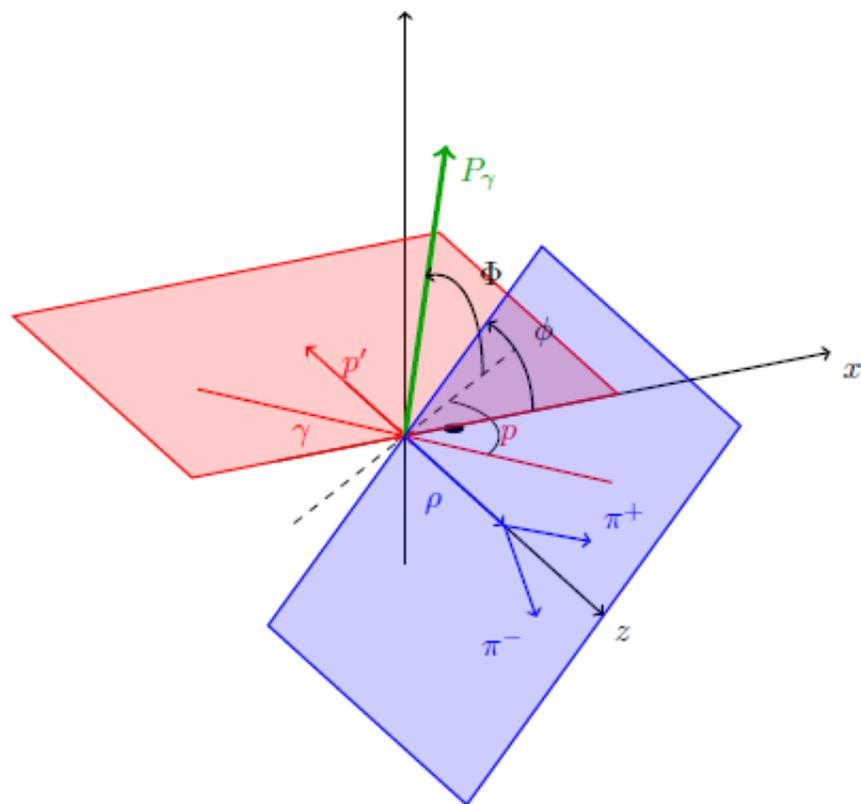

The ratio of η'/η asymmetries should be exactly 1 without hidden strangeness (eg, ϕ exchange). With expected levels of $N \rightarrow N\phi$, the ratio should be less 1.01 . <https://arxiv.org/abs/1704.07684>

Thesis topic of Tegan Beattie (U. Regina)

Including the 4x larger 2018 dataset would allow a more convincing check that η and η' photoproduction are similar as expected.

Spin Density Matrix Elements (SDME's) for Vector Meson Photo-production

Also tests the reaction mechanism for photo-production, but now including the richer information provided by decay of a vector meson.

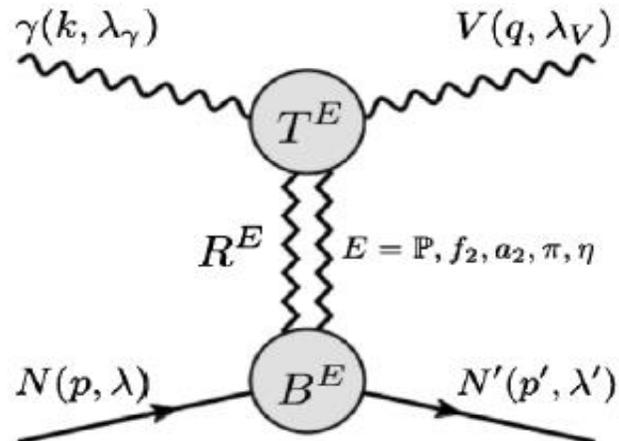

See also A. Austregesilo MENU 2019: <https://registration.mcs.cmu.edu/event/1/contributions/41/>

JPAC SDME Model

In the JPAC Regge model of vector meson photo-production, the leading trajectories are

$I^{G\eta\tau} J^{PC}$	$I^{G\eta\tau} J^{PC}$	$I^{G\eta\tau} J^{PC}$
$a_2: 1^{-++}2^{++}$	$\pi: 1^{--}0^{-+}$	$a_1: 1^{--}1^{++}$
$f_2: 0^{++}2^{++}$	$\eta: 0^{+-}0^{-+}$	$f_1: 0^{+-}1^{++}$

- Natural parity exchange from the Pomeron is also included.
- Meson-nucleon and meson radiative decay widths are taken from literature, estimated, or ignored as negligible.
- SLAC data at 9.3 GeV are used for constraints, the ρ data having significantly smaller statistical errors than for ω , ϕ .

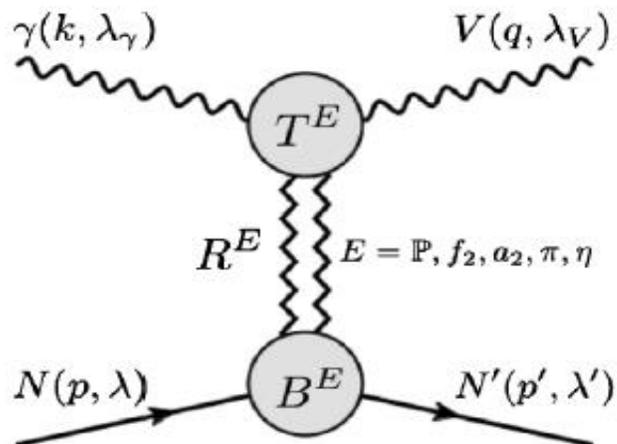

PRD 97, 094003 (2018)
<https://arxiv.org/abs/1802.09403>

JPAC SDME Model

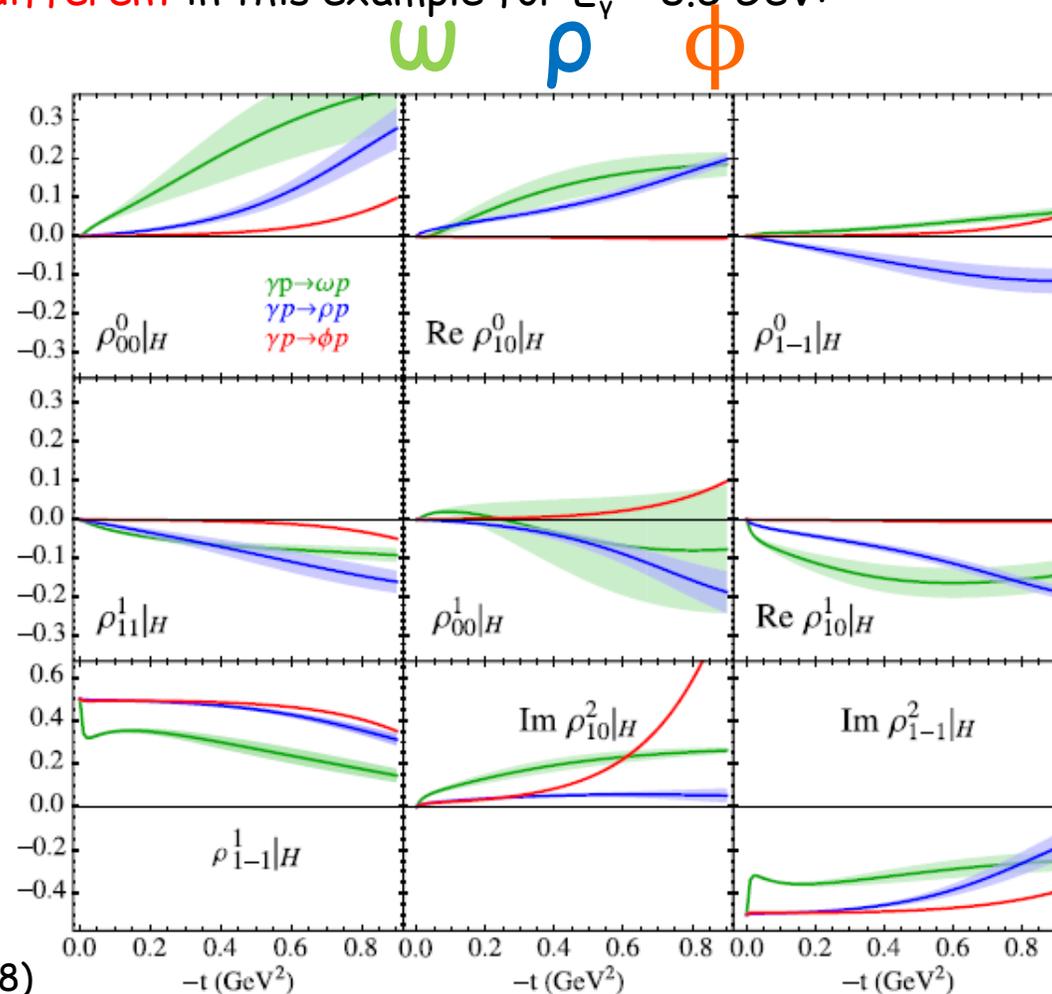

In the JPAC Regge model of vector meson photo-production, the leading trajectories are

$I^{G\eta\tau} J^{PC}$	$I^{G\eta\tau} J^{PC}$	$I^{G\eta\tau} J^{PC}$
$a_2: 1^{-++}2^{++}$	$\pi: 1^{--}0^{-+}$	$a_1: 1^{--}1^{++}$
$f_2: 0^{+++}2^{++}$	$\eta: 0^{+-}0^{-+}$	$f_1: 0^{+-}1^{++}$

- Natural parity exchange from the Pomeron is also included.
- Meson-nucleon and meson radiative decay widths are taken from literature, estimated, or negligible and dropped.
- SLAC data at 9.3 GeV are used for constraints, the ρ data having significantly smaller statistical errors than for ω , ϕ .

Although these vector mesons have the same J^{PC} , the predicted SDME's, and their uncertainties, are quite different in this example for $E_\gamma = 8.5$ GeV:

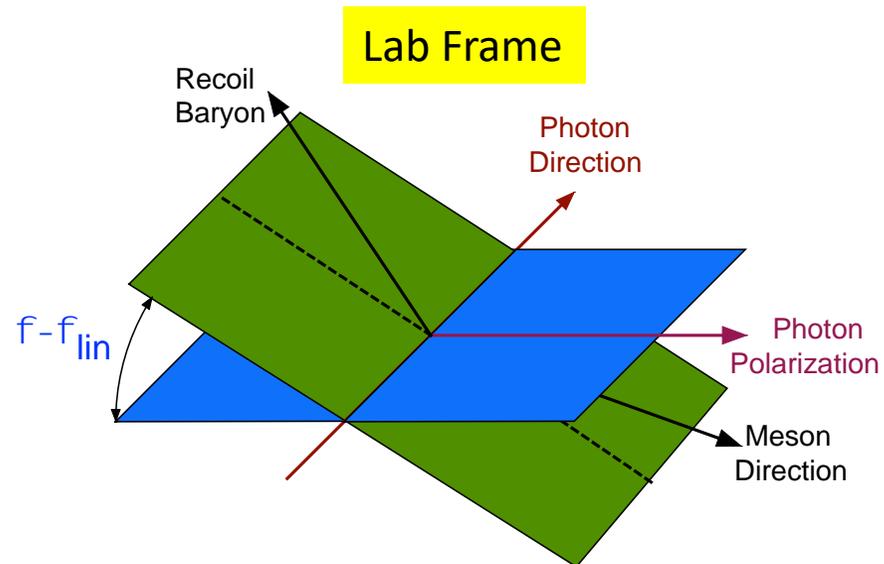

PRD 97, 094003 (2018)
<https://arxiv.org/abs/1802.09403>

Coordinate Systems

In the Σ asymmetry slides, we saw the beam spin asymmetry was extracted from the yield variation proportional to $\cos[2(\phi-\phi_s)]$ where

- ϕ is the meson production plane, and
- ϕ_s is the polarization plane.

The decay contains no information for spin 0.

Coordinate Systems

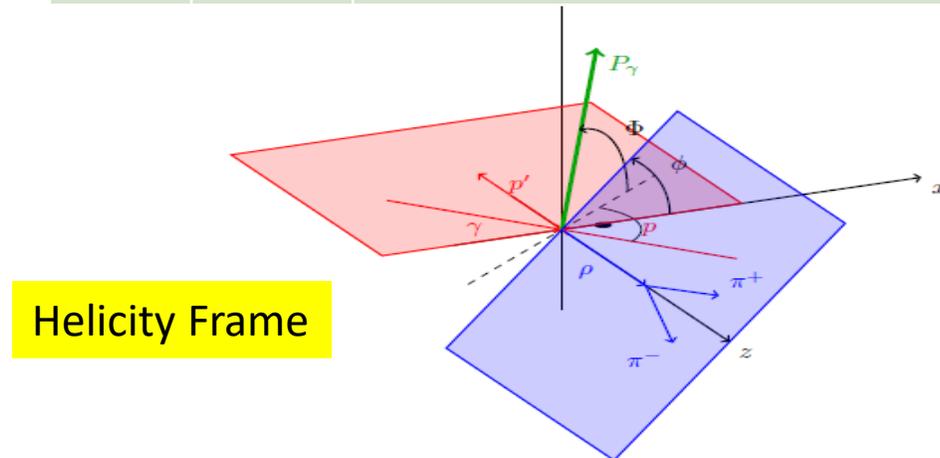

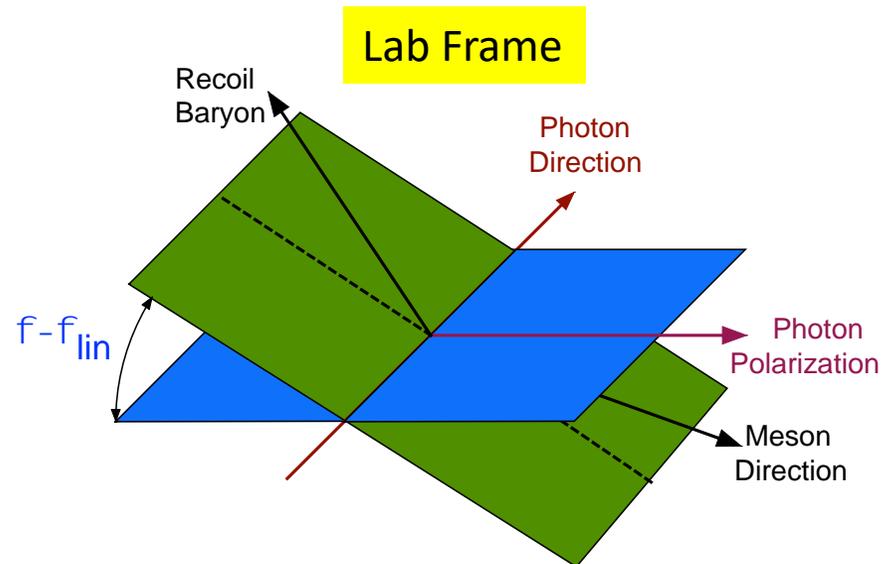

In the Σ asymmetry slides, we saw the beam spin asymmetry was extracted from the yield variation proportional to $\cos[2(\phi-\phi_s)]$ where

- ϕ is the meson production plane, and
- ϕ_s is the polarization plane.

The decay contains no information for spin 0.

Because the decay distribution of spin 1 particles depends on the final polarization, it makes sense to transfer into the helicity frame. There are two additional decay angles and some potentially confusing nomenclature overlaps:

Σ	SDME's	Description
ϕ		Meson production plane
ϕ_s		Linear Polarization plane
$\phi - \phi_s$	Φ	Difference between production and polarization planes.
---	ϕ	Azimuthal decay angle in helicity frame
---	θ	Polar decay angle in helicity frame

How the SDME's are Measured: ω example

The SDMEs describe the polarization of the vector meson.

The angular distribution for the vector decay in the helicity frame is

$$\frac{dN}{d \cos \theta d\phi} \equiv W(\cos \theta, \phi)$$

where

$$W(\cos \theta, \phi) = W^0(\cos \theta, \phi) + \sum_{i=1}^3 P_{\gamma}^i W^i(\cos \theta, \phi)$$

Assuming only linear polarization,

$$P_{\gamma}^{\text{vec}} = P_{\gamma}(-\cos 2\Phi - \sin 2\Phi, 0)$$

Then for the hadronic ω decay:

$$W_h^0(\cos \theta, \phi, \rho^0) = \frac{3}{4\pi} \left[\frac{1}{2} (1 - \rho_{00}^0) + \frac{1}{2} (3\rho_{00}^0 - 1) \cos^2 \theta - \sqrt{2} \text{Re} \rho_{10}^0 \sin 2\theta \cos \phi - \rho_{1-1}^0 \sin^2 \theta \cos 2\phi \right]$$

$$W_h^1(\cos \theta, \phi, \rho^1) = \frac{3}{4\pi} \left[\rho_{11}^1 \sin^2 \theta + \rho_{00}^1 \cos^2 \theta - \sqrt{2} \text{Re} \rho_{10}^1 \sin 2\theta \cos \phi - \rho_{1-1}^1 \sin^2 \theta \cos 2\phi \right]$$

$$W_h^2(\cos \theta, \phi, \rho^2) = \frac{3}{4\pi} \left[\sqrt{2} \text{Im} \rho_{10}^2 \sin 2\theta \sin \phi + \text{Im} \rho_{1-1}^2 \sin^2 \theta \sin 2\phi \right]$$

There are 9 linearly independent parameters; 6 require beam polarization.

How the SDME's are Measured: w example

Plots like this for each bin in -t.

The SDMEs describe the polarization of the vector meson.
The angular distribution for the vector decay in the helicity frame is

$$\frac{dN}{d \cos \theta d\phi} \equiv W(\cos \theta, \phi)$$

where

$$W(\cos \theta, \phi) = W^0(\cos \theta, \phi) + \sum_{i=1}^3 P_{\gamma}^i W^i(\cos \theta, \phi)$$

Assuming only linear polarization,

$$P_{\gamma}^{\text{vec}} = P_{\gamma}(-\cos 2\Phi - \sin 2\Phi, 0)$$

Then for the hadronic ω decay:

$$W_h^0(\cos \theta, \phi, \rho^0) = \frac{3}{4\pi} \left[\frac{1}{2} (1 - \rho_{00}^0) + \frac{1}{2} (3\rho_{00}^0 - 1) \cos^2 \theta - \sqrt{2} \text{Re} \rho_{10}^0 \sin 2\theta \cos \phi - \rho_{1-1}^0 \sin^2 \theta \cos 2\phi \right]$$

$$W_h^1(\cos \theta, \phi, \rho^1) = \frac{3}{4\pi} \left[\rho_{11}^1 \sin^2 \theta + \rho_{00}^1 \cos^2 \theta - \sqrt{2} \text{Re} \rho_{10}^1 \sin 2\theta \cos \phi - \rho_{1-1}^1 \sin^2 \theta \cos 2\phi \right]$$

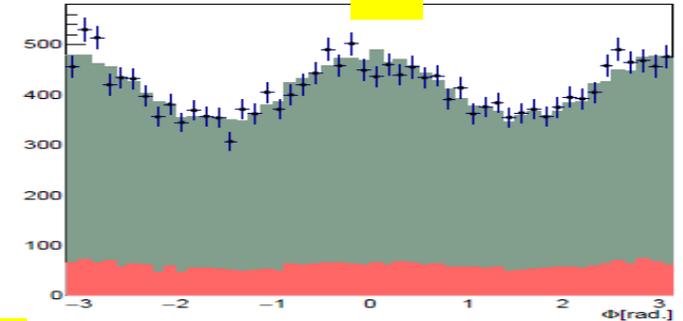

$$W_h^2(\cos \theta, \phi, \rho^2) = \frac{3}{4\pi} \left[\sqrt{2} \text{Im} \rho_{10}^2 \sin 2\theta \sin \phi + \text{Im} \rho_{1-1}^2 \sin^2 \theta \sin 2\phi \right]$$

There are 9 linearly independent parameters; 6 require beam polarization.

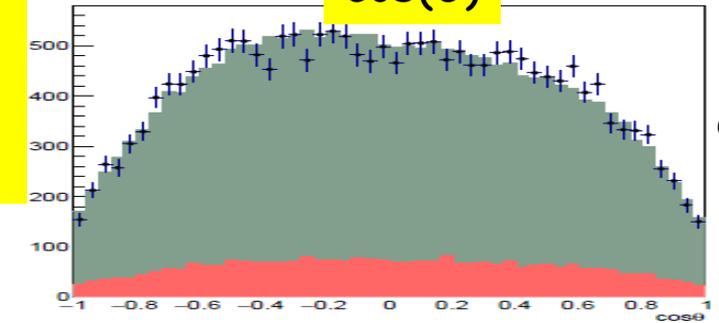

Although there is cancellation of some instrumental asymmetries when we combine data for Para and Perp, the SDME's are a bigger challenge than the Σ asymmetry because acceptance corrections are needed in ϕ and θ .

M. Staib, PhD thesis, Sept 2017, CMU

Φ

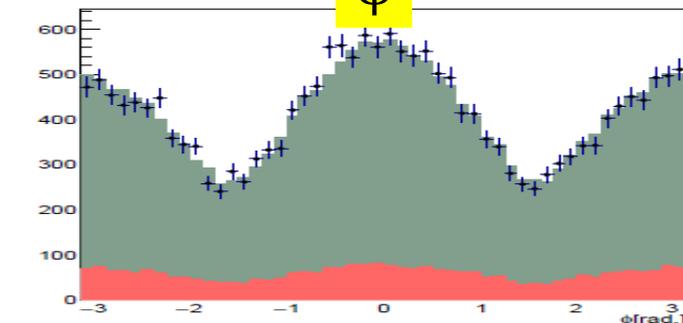

$\cos(\theta)$

Fit quality is Good!

ϕ

Parity Asymmetry

The parity asymmetry has a similar physical interpretation to Σ :

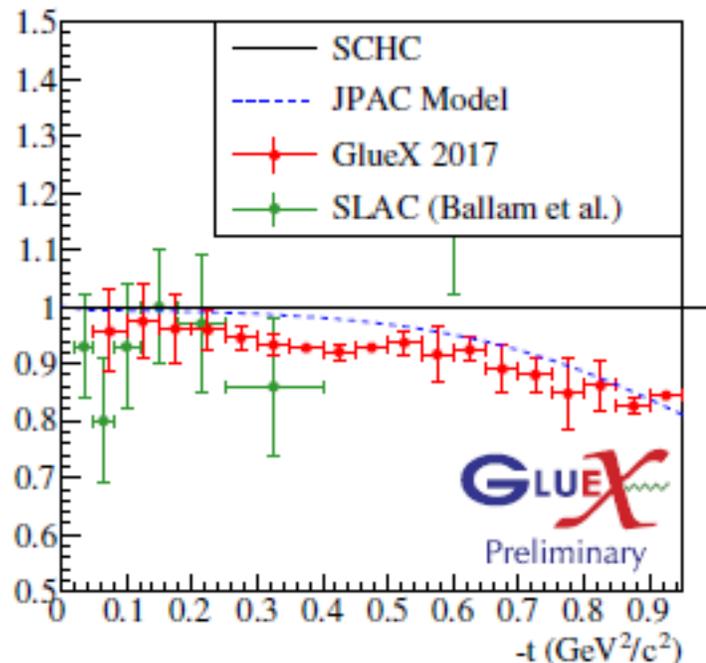

$$P_\sigma = \frac{\sigma_{N-\sigma}^N - \sigma_{N+\sigma}^U}{\sigma_{N+\sigma}^N + \sigma_{N-\sigma}^U} = 2\rho_{1-1}^1 - \rho_{00}^1$$

For the ρ , it will be particularly useful to transform to linear combinations which are Natural or Unnatural. (next slide)

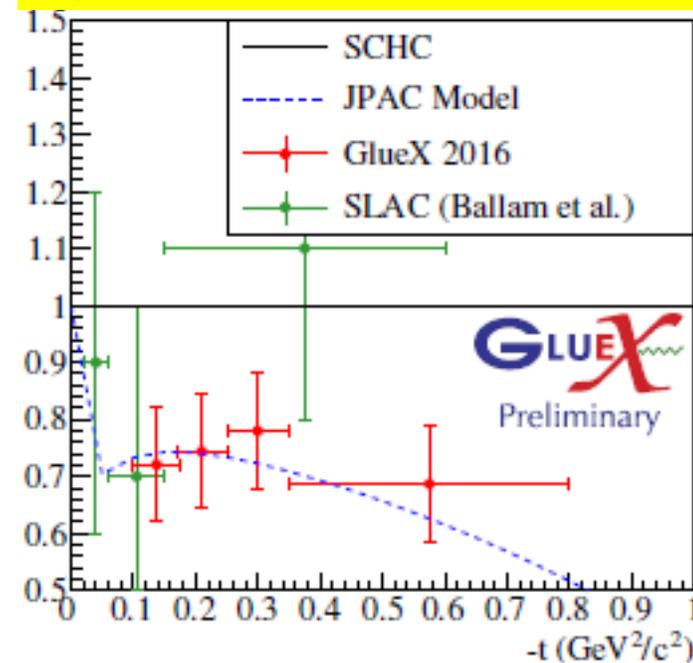

$$\rho_{ik}^{N,U} = \frac{1}{2}(\rho_{ik}^0 \mp (-1)^i \rho_{-ik}^1)$$

Schilling *et al.* [Nucl. Phys. B, 15 (1970) 397]

ρ : Natural parity dominates for the ρ at low $-t$.

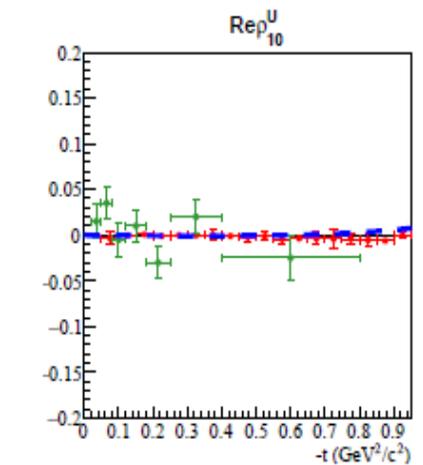

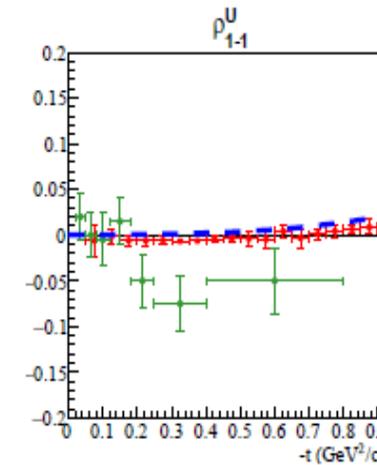

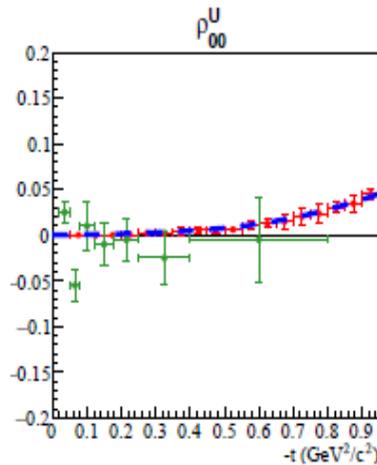

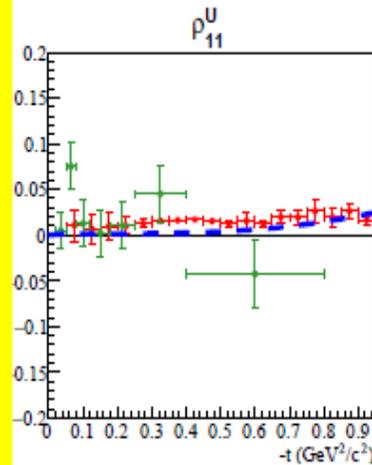

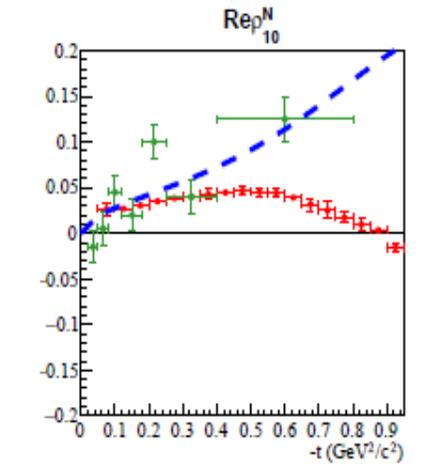

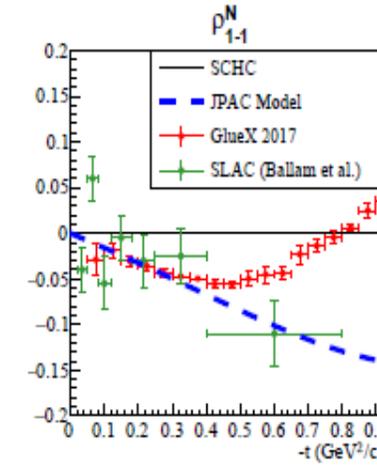

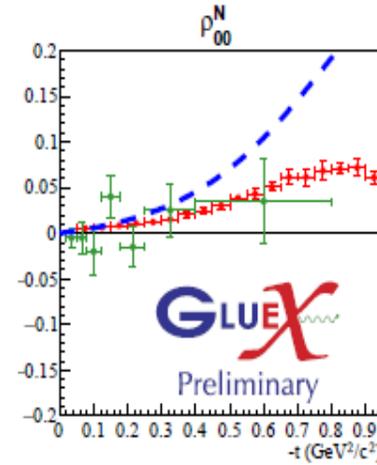

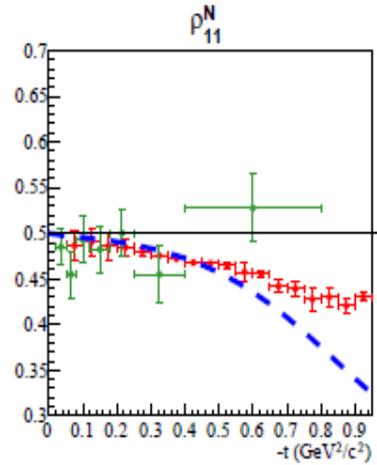

ω : Unnatural parity exchange is significant even at low $-t$ for the ω .

This unnatural parity exchange may be from π^0 exchange due in part to the large BR for $\omega \rightarrow \pi^0 \gamma$.

Natural and Unnatural Projections for the ρ

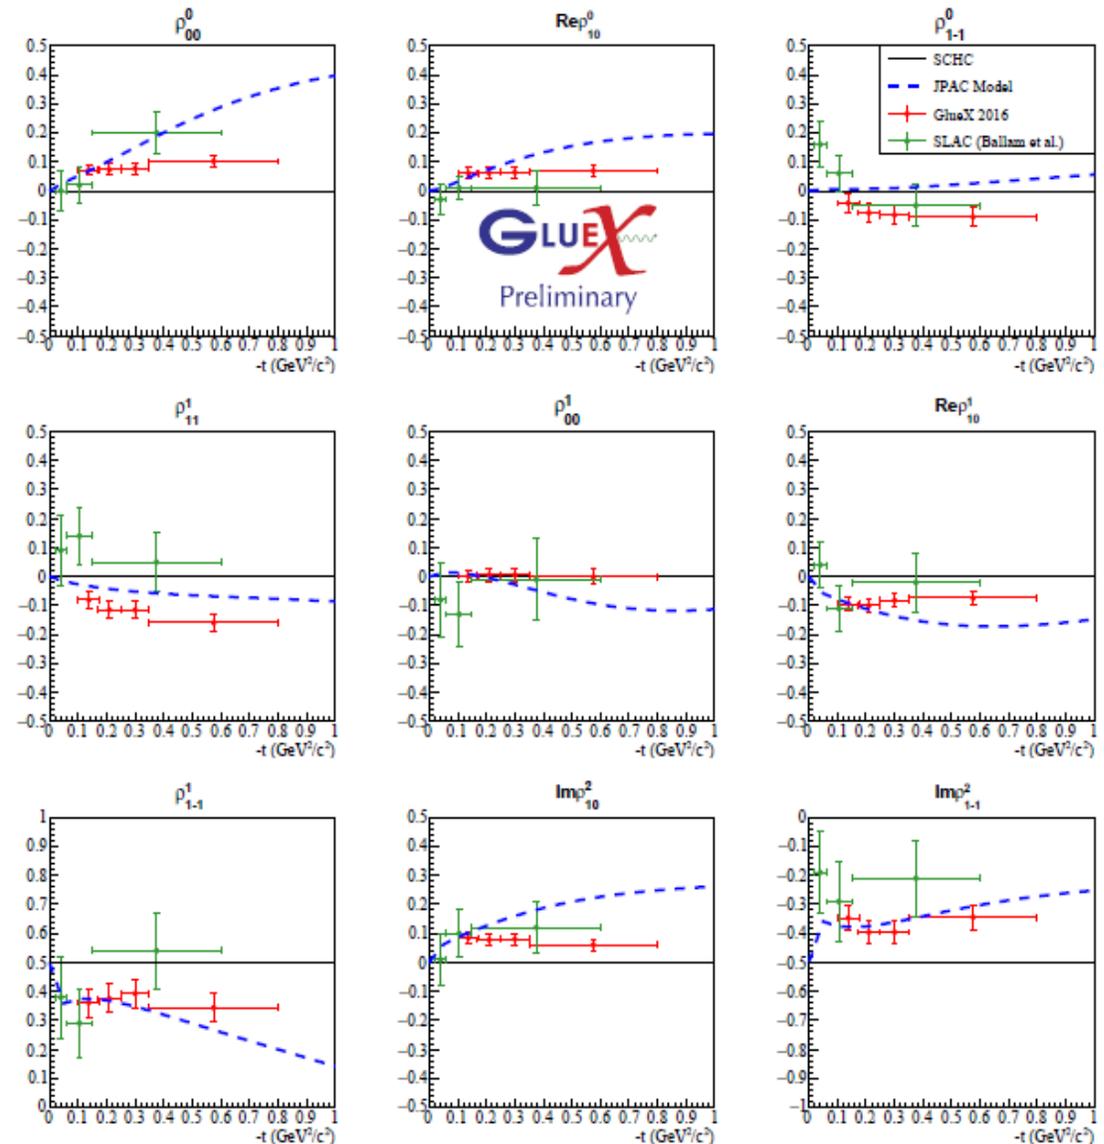

For the ρ , all the natural exchange terms (top) are larger than the unnatural exchange terms (bottom).

- SCHC only works in $-t \rightarrow 0$ limit.
- GlueX ρ data have enormously improved statistics. (Important since SDME's are $\ll 1$!)
- JPAC model works fairly well below $-t \sim 0.5$.
- Even natural exchange has unexpected behavior at $-t > 0.5$

JPAC Model vs GlueX Data for w

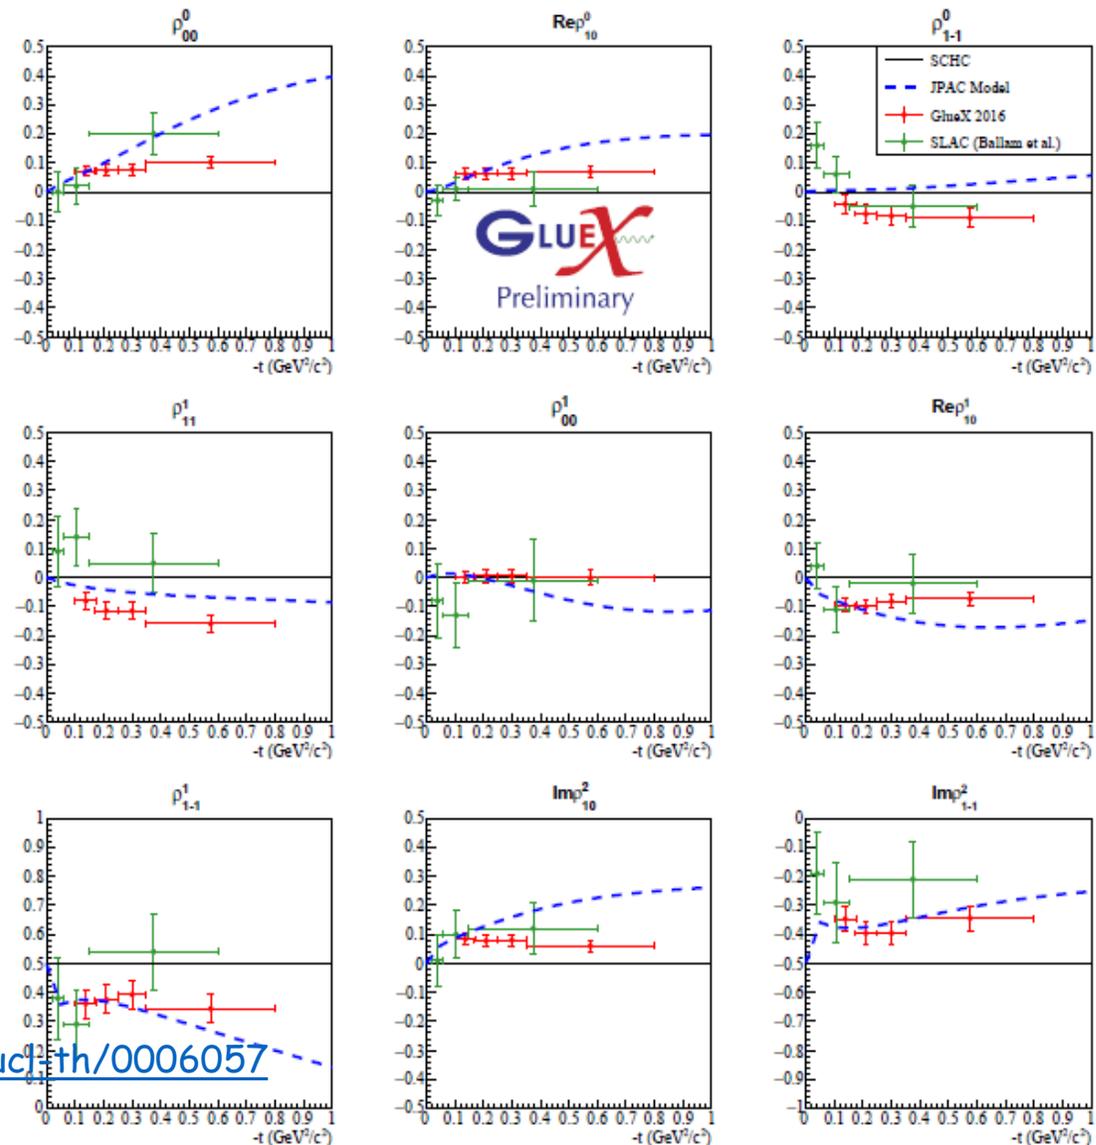

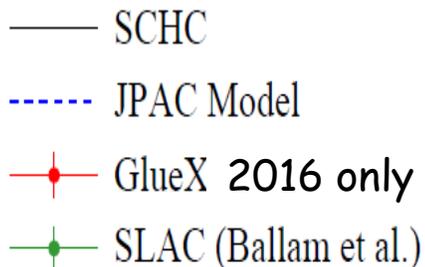

For the w , on the right are the regular SDME's
(ie not the Natural and Unnatural linear combinations):

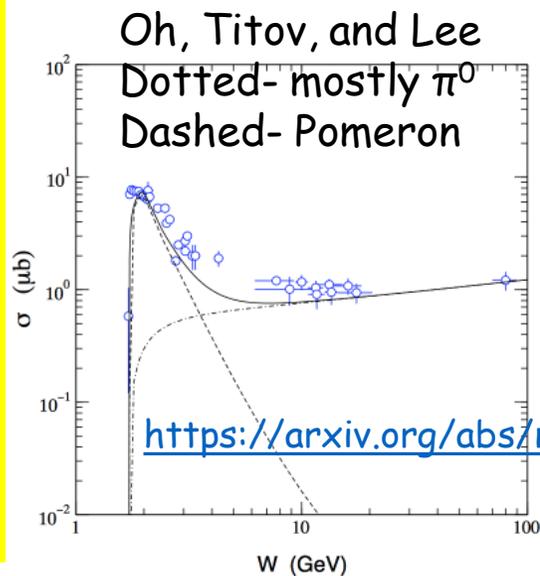

- SCHC only works in $-t \rightarrow 0$ limit.
- GlueX w data have significantly improved statistics (Important since SDME's are $\ll 1$)
- JPAC model agreement with preliminary data is only qualitative.
- No breakdown of relative contributions in JPAC paper, but earlier OTL model suggests w results are sensitive to π^0 vs Pomeron

JPAC Model vs GlueX Data for w

For the w , on the right are the regular SDME's
(ie not the Natural and Unnatural linear combinations):

- SCHC only works in $-t \rightarrow 0$ limit.
- GlueX w data have significantly improved statistics (Important since SDME's are $\ll 1$)
- JPAC model agreement with preliminary data is only qualitative.
- No breakdown of relative contributions in JPAC paper, but earlier OTL model suggests w results are sensitive to π^0 vs Pomeron

Summary

- GlueX is a fixed target, linearly polarized photo-production facility with the beam energy, acceptance, and intensity to search for hybrid mesons in the expected mass range of 1.5-2.5 GeV/c^2 .
- The detectors and beamline instrumentation are all working well: eg, exclusive η' photo-production is reconstructed with low background by detecting 5 tracks+showers with a total efficiency of $\sim 10\%$.

Σ Asymmetries:

- Our commissioning data were previously analyzed to extract beam asymmetry (Σ) measurements of π^0 and η photo-production:
 - i. first Σ measurements on the η in this beam energy range (**previously published**)
 - ii. natural parity exchange (ie vectors) dominates for $-t$ below 1 $(\text{GeV}/c)^2$.
- Production data with 8x our earlier statistics have now been analyzed to extract Σ (**paper submitted to PRC**)
 - i. first Σ measurements on the η' in this beam energy range .
 - ii. natural parity exchange also dominates for the η' , but a detailed comparison of η vs η' will require much more statistics.
 - iii. we have more precise results for the π^0 and η , approaching a systematic limit of a few percent at low $-t$.

SDME's:

- Preliminary SDME's for ρ , ω , and ϕ have been produced.
 - i. For the ρ , impressive statistics and good agreement with JPAC model below $-t \sim 0.5 (\text{GeV}/c)^2$.
 - ii. For the ω , good statistics but only qualitative agreement with the Regge model by JPAC.

$-t_{\min}$ vs mass

$-t_{\min}$ vs mass

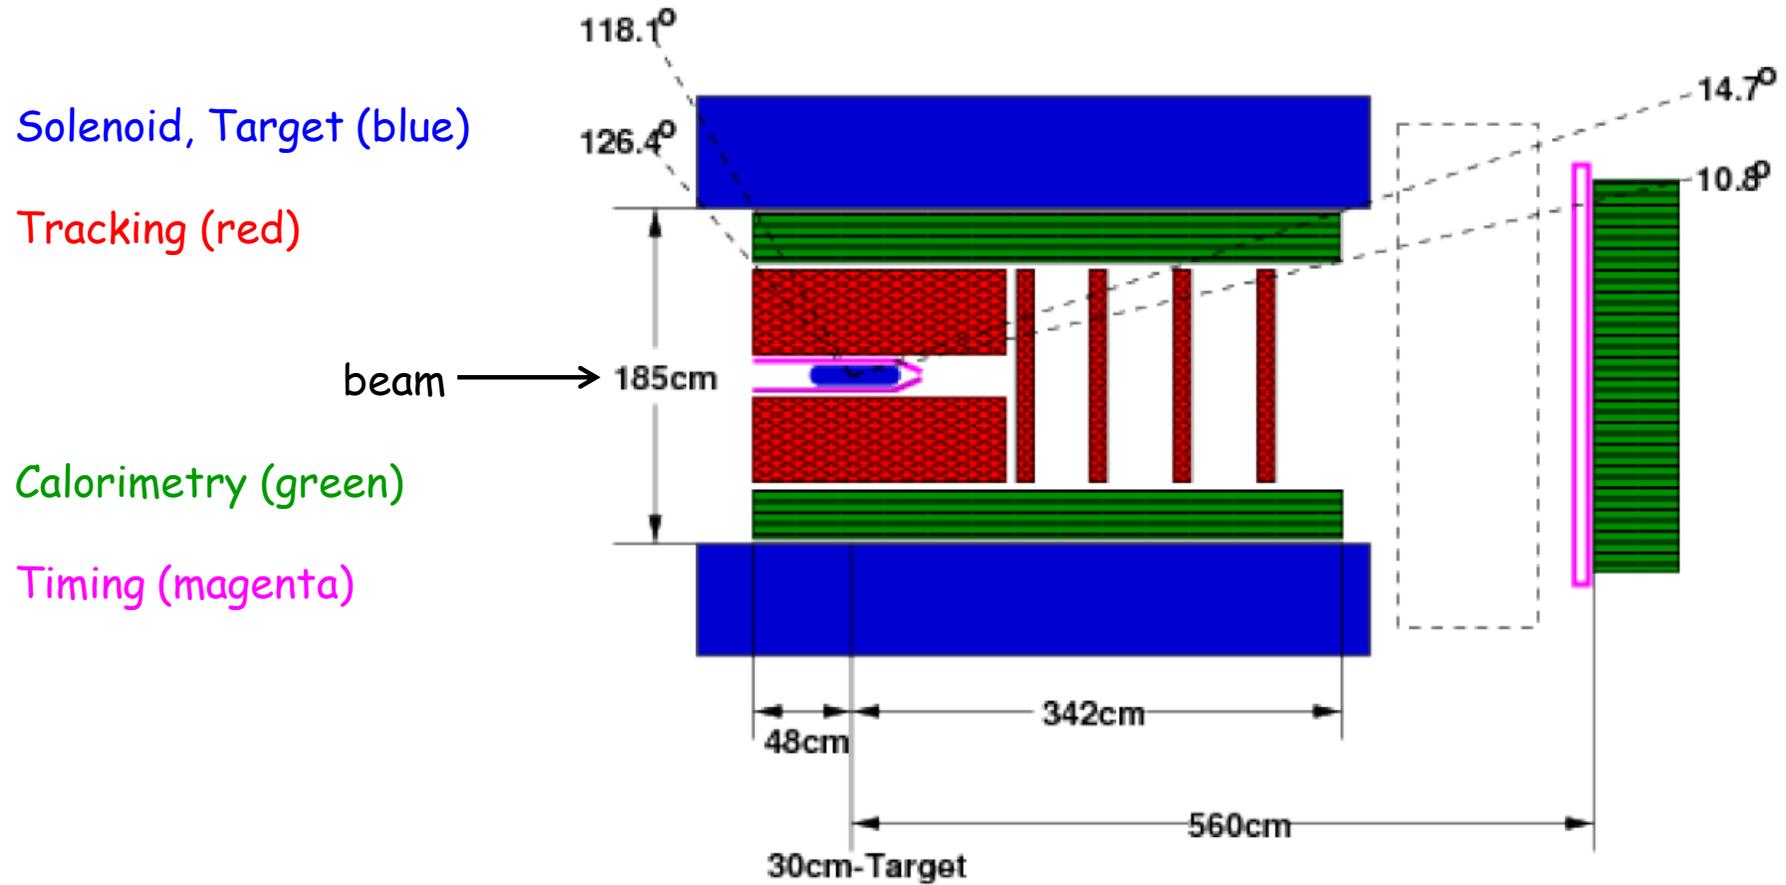

Photon Beamline

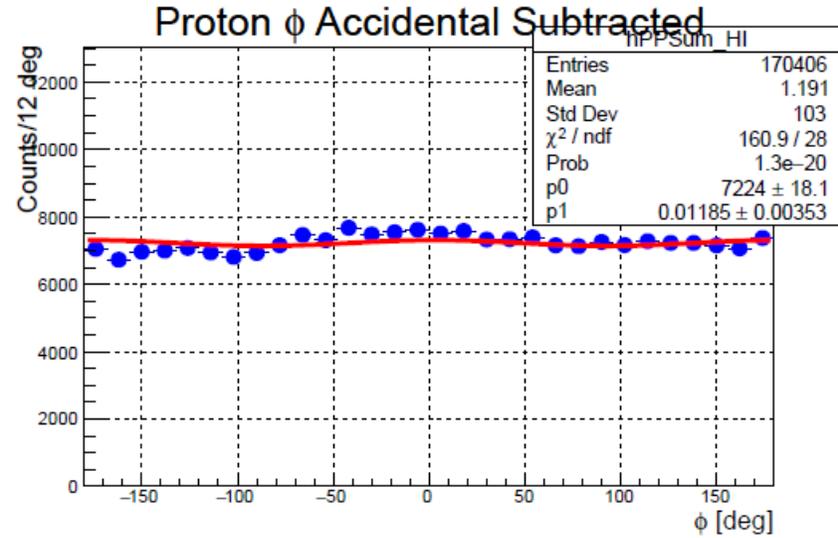

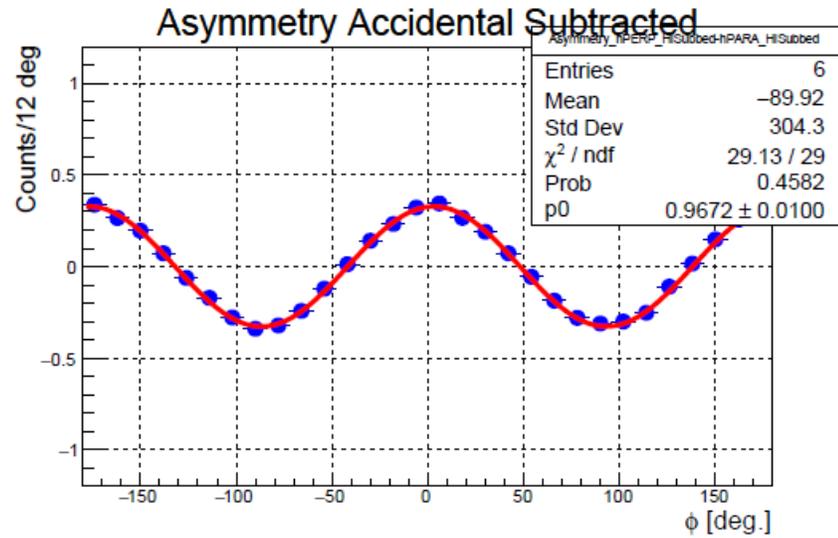

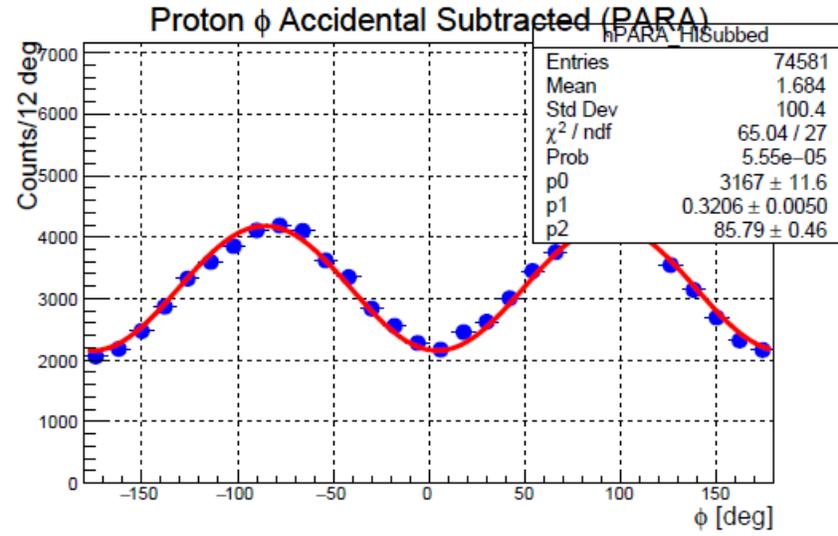

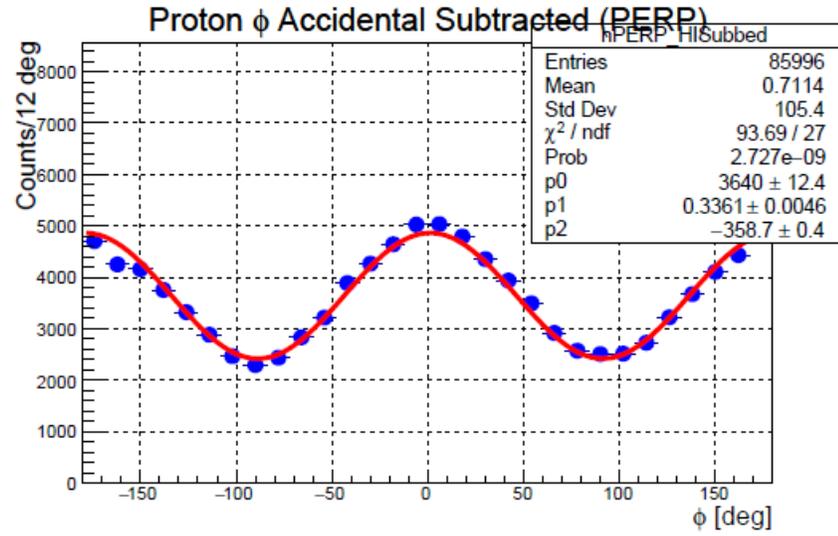

9 GeV Polarized Photon Beam

- Coherent Bremsstrahlung on thin diamond
- Energy tagged by scattered electrons
- Collimator to suppress incoherent part
- Linear polarization in peak $P_\gamma \approx 40\%$, measured by Triplet polarimeter:
 $\gamma e^- \rightarrow e^- e^+ e^-$
- Beam intensity: $1 - 5 \cdot 10^7 \gamma/s$ in peak

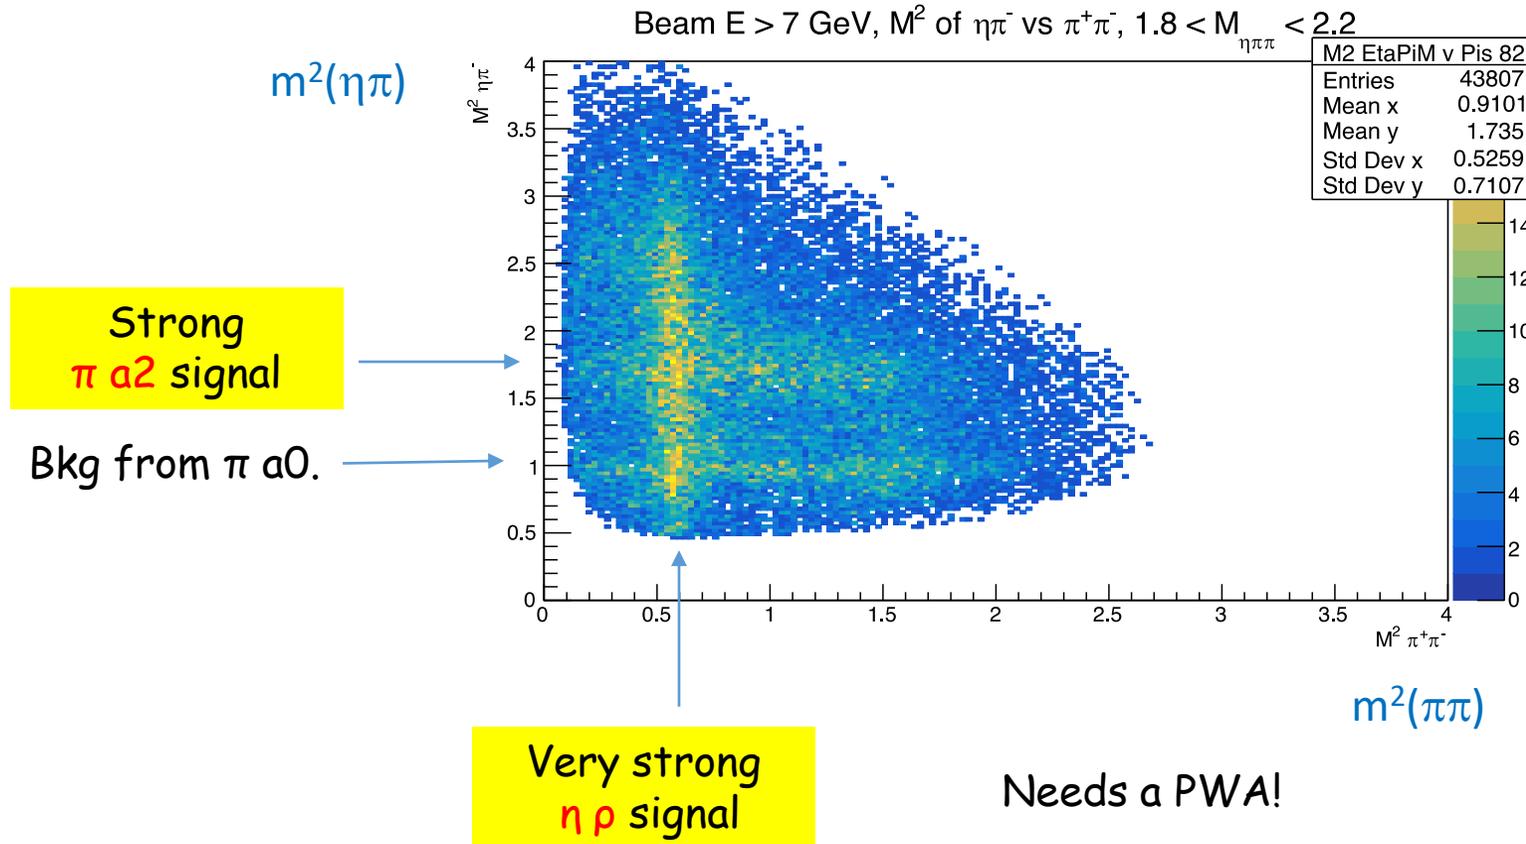

GlueX Detector

$M(\eta\pi)$ vs $M(2\pi)$ in $\gamma+p \rightarrow \rho\eta\pi^+\pi^-$

$M(\eta\pi\pi)$ cut to meson masses $\sim 2 \text{ GeV}/c^2$

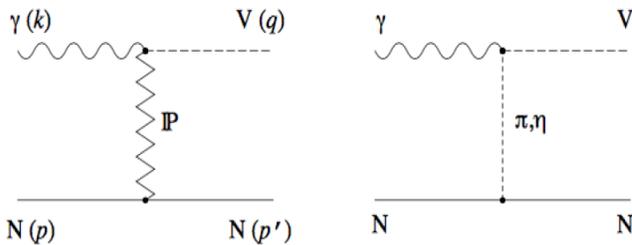

We're just getting started with the fairly complex event selection.

SDME's of Vector Mesons

In the OTL model, the w SDMEs are sensitive to the relative amounts of Pomeron and PS meson exchange (mostly π^0 due to the large value of $g_{\pi NN}$).

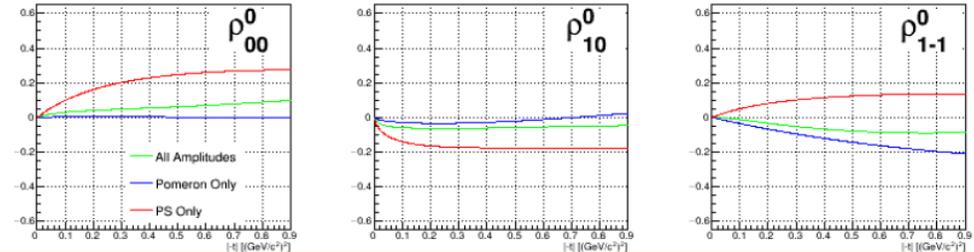

Oh, Titov, Lee model

$$I_{tot} = I_{\mathbb{P}} + I_{\pi} + I_{\eta}$$

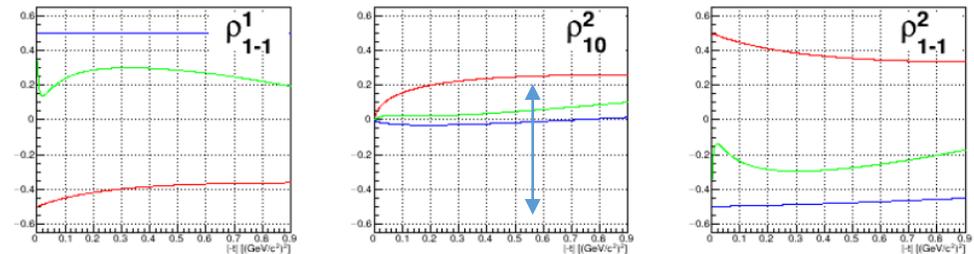

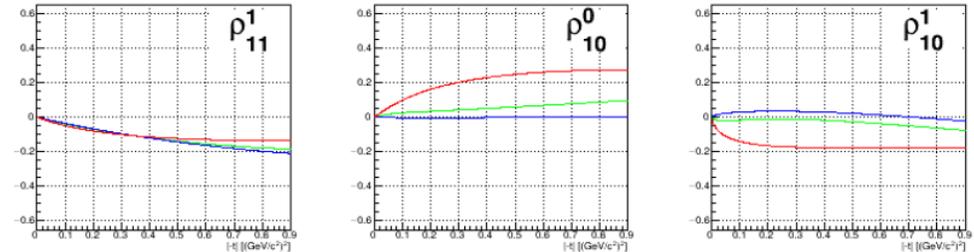

Model the nonresonant amplitude as the sum of Pomeron and Pseudoscalar exchange

Phys. Rev. C 63 (2001) 025201

Blue – Pomeron Only Red – Pseudoscalar Only Green – Combined

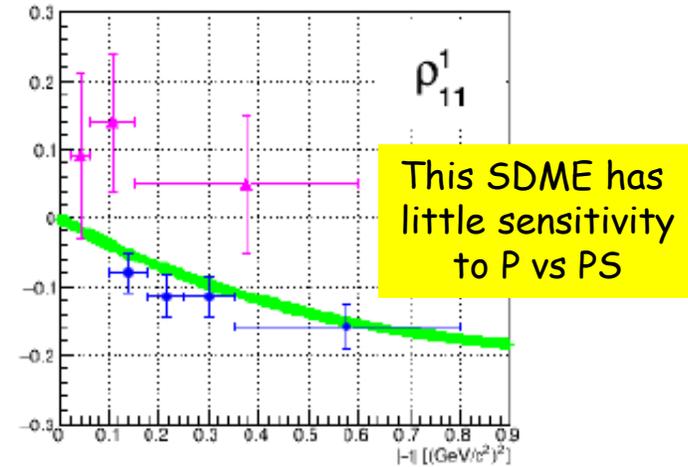

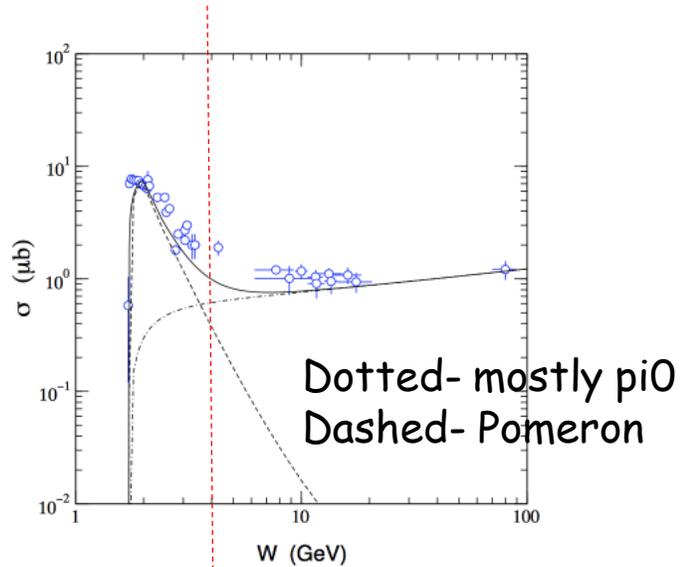

-t dependence of w SDMEs

Note the often very different behavior predicted for Blue/Pomeron vs Red/PS exchange.

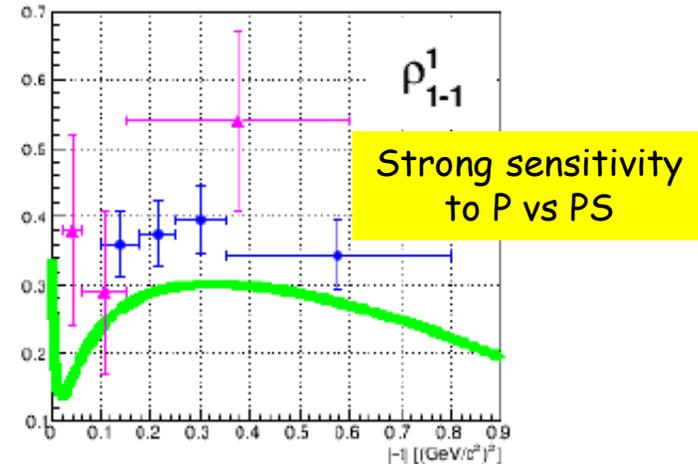

SDME's of ω Mesons

Broadly speaking, results are consistent with the dominance of Pomeron exchange at our beam energy and range of $-t$.

In the context of the OTL model, a small adjustment in the relative strengths of the Pomeron and π^0 may be needed.

Abstract Submitted to Hadron 2019

Selected ~~Overview of~~ Light Meson Results from the GlueX Experiment D. Mack for the GlueX Collaboration, TJNAF

The GlueX experiment in Hall D at Jefferson Lab consists of a well-instrumented photon beamline in conjunction with a solenoidal spectrometer providing near-hermetic coverage for charged particles and photons. Since 2016, the experiment has had several run periods with a 9 GeV linearly polarized photon beam on a 30cm liquid hydrogen target, completing its initial low-intensity program. Light (i.e., $< 1.05 \text{ GeV}/c^2$) meson studies have been critical to commissioning the GlueX detector, elucidating the photo-production reaction mechanism in this photon energy range, and testing the event selection techniques needed to search for exotic hybrid mesons. We have measured the beam asymmetries for photo-production of pseudo-scalar mesons including π^0 , η , and η' , and have preliminary results for the Spin Density Matrix Elements (SDMEs) for the vector mesons ω , ρ , and ϕ . ~~Cross-section determinations are in progress for all these mesons, usually in more than one decay branch, and with 3-7 particles exclusively detected in the final state. The outlook appears encouraging for GlueX to measure precise, competitive Dalitz plots for $\eta \rightarrow 3\pi$ and $\eta' \rightarrow \eta 2\pi$. The latter $\eta' \rightarrow \eta 2\pi$ studies are synergistic with exploratory studies of the continuum $M(\eta 2\pi)$ spectrum between 1.5 to 2.5 GeV/c^2 where we plan to search for hybrid exotic mesons.~~
