

The Flatte Parametrization of the $a_0(980)$

Curtis A. Meyer

December 18, 2020

In the Crystal Barrel paper on $\bar{p}p \rightarrow K_L K^\pm \pi^\mp$ [1], a Flatte parametrization [2] is used for the $a_0(980)$ to accurately account for both the $\eta\pi$ and the $K\bar{K}$ decay. That parametrization is given as

$$F_0(m) = \beta'_0 \frac{\begin{pmatrix} g_1 \\ g_2 \end{pmatrix}}{m_0^2 - m^2 - i(\rho_1(m)g_1^2 + \rho_2(m)g_2^2)}, \quad (1)$$

where m_0 is the nominal mass of the $a_0(980)$, m is the running mass of the $a_0(980)$, g_1 and g_2 are the couplings to the $\eta\pi$ and $K\bar{K}$ channels. The paper and an earlier Crystal Barrel paper on the analysis of $\eta\pi^0\pi^0$ [3] final states finds

$$\begin{aligned} g_{\eta\pi} &= 353 \text{ MeV} \\ g_{K\bar{K}} &= 311 \text{ MeV}. \end{aligned}$$

That paper also finds a pole mass of the a_0 of $m_{a_0} = 984.45$ MeV. The parameter β'_0 describes the production of the resonance from the initial $p\bar{p}$ and the $\rho_i(m)$ s are the phase space available for the decay with an a_0 of mass m , and is given as

$$\rho_i(m) = \frac{2q(m)}{m}, \quad (2)$$

where the decay momentum of the a_0 to daughters of mass m_1 and m_2 is given as

$$q(m) = \frac{\sqrt{[m^2 - (m_1 - m_2)^2] [m^2 - (m_1 + m_2)^2]}}{2m}. \quad (3)$$

What will ultimately replace the Breit-Wigner for the $a_0(980)$ is $\rho | F |^2$.

For the case of $a_0 \rightarrow K_S K_S$, we would have the decay momentum being

$$\begin{aligned} q_{K\bar{K}}(m) &= \frac{1}{2} \sqrt{m^2 - 4m_{K_S}^2} \quad m > 2m_{K_S} \\ q_{K\bar{K}}(m) &= 0 \quad m \leq 2m_{K_S}. \end{aligned}$$

and for the decay to $\eta\pi$, we have

$$q_{\eta\pi}(m) = \frac{\sqrt{[m^2 - (m_\eta - m_\pi)^2] [m^2 - (m_\eta + m_\pi)^2]}}{2m}.$$

From these, the phase space factors are

$$\begin{aligned}\rho_{K\bar{K}}(m) &= \sqrt{1 - \left(\frac{2m_{K_S}}{m}\right)^2} & m > 2m_{K_S} \\ \rho_{K\bar{K}}(m) &= 0 & m \leq 2m_{K_S}.\end{aligned}$$

and

$$\rho_{\eta\pi}(m) = \frac{\sqrt{[m^2 - (m_\eta - m_\pi)^2][m^2 - (m_\eta + m_\pi)^2]}}{m^2}.$$

So, the Flatté formulation for the $K\bar{K}$ decay will be

$$F_{K\bar{K}}(m) = \frac{g_{K\bar{K}}}{m_{a_0}^2 - m^2 - i(\rho_{\eta\pi}(m)g_{\eta\pi}^2 + \rho_{K\bar{K}}(m)g_{K\bar{K}}^2)},$$

and the function to replace the Breit-Wigner form is

$$BW(m) = c \rho_{K\bar{K}}(m) |F_{K\bar{K}}(m)|^2, \quad (4)$$

where c is a normalization constant. This function will be 0 for $m \leq 2m_{K_S}$, and then turn on after that, yielding a bump above 1 GeV.
